Abstract

The present paper deals with non Newtonian viscoelastic flows of Oldroyd-B type in thin domains. Such geometries arise for example in the context of lubrication. More precisely, we justify rigorously the asymptotic model obtained heuristically by proving the mathematical convergence of the Navier-Stokes/Oldroyd-B system towards the asymptotic model.

Keywords: Viscoelastic fluids, Thin film, Oldroyd model, Lubrication flow, Asymptotic analysis.

1 Introduction

This paper concerns the study of a viscoelastic fluid flow in a thin gap, the motion of which is imposed due to non homogeneous boundary conditions.

When a Newtonian flow is contained between two close given surfaces in relative motion, it is well known that it is possible to replace the Stokes or Navier-Stokes equations governing the fluid's motion by a simpler asymptotic model. The asymptotic pressure is proved to be independent of the normal direction to the close surfaces and obeys the Reynolds thin film equation whose coefficients include the velocities, the geometrical description of the surrounding surfaces and some rheological characteristics of the fluid. As a following step, the computation of this pressure allows an asymptotic velocity of the fluid to be easily computed. Such asymptotic procedure first proposed in a formal way by Reynolds [2] has been rigorously confirmed for Newtonian stationary flow [1], and then generalized in a lot of situations covering numerous applications for both compressible fluid [14], unsteady cases [3], multifluid flows [15].

It is well known however that in numerous applications, the fluid to be considered is a non Newtonian one. This is the case for numerous biological fluids, modern lubricants in engineering applications due to the additives they contain, polymers in injection or molding process. In all of these applications, there are situations in which the flow is anisotropic. It is usual to take

account of this geometrical effect in order to simplify the three-dimensional equations of the motion, trying to recover two dimensional Reynolds like equation with respect to the pressure only. Such procedures are more often heuristic ones. Nevertheless, some mathematical works appeared in the literature to justify them. They include thin film asymptotic studies of Bingham flow [9], quasi Newtonian flow (Carreau's law, power law or Williamson's law, in which various stress-velocity relations are chosen: [7], [6], [16]) and also micro polar ones [5]. It has been possible to obtain rigorously some thin film approximation for such fluids using a so called generalized Reynolds equation for the pressure.

However in the preceding examples, elasticity effects are neglected. Introduction of such viscoelastic behavior is characterized by the Deborah number which is related to the relaxation time. One of the most popular laws is the Oldroyd-B model whose constitutive equation is an interpolation between purely viscous and purely elastic models, thus introducing an additional parameter which describes the relative proportion of both behaviors. A formal procedure has been proposed in [4]. However, the asymptotic system so obtained lacks the usual characteristic of classical generalized Reynolds equation as it has not been possible to gain an equation in the asymptotic pressure only. Both velocity u^* and pressure p^* are coupled by a non linear system.

It is the goal of this paper to justify rigorously this asymptotic system. Section 2 is devoted to the precise statement of the 3-D problem. One difficulty has been to find an existence theorem for the general Oldroyd-B model, acting as a starting point for the mathematical procedure. Most of the existence theorems, however, deal with small data or small time assumptions. To control this kind of property with respect to the smallness of the gap appears somewhat difficult. So we are led to consider a more particular Oldroyd-B model, for which unconditional existence theorem has been proved [13]. Moreover, a specific attention is devoted to the boundary conditions to be introduced both on the velocity and on the stress. The goal is to use "well prepared" boundary conditions so as to prevent boundary layer on the lateral side of the domain.

In Section 3, after suitable scaling procedure, asymptotic expansions of both pressure, viscosity and stress are introduced, taking into account the previous formal results from [4]. Section 4 is mainly concerned with the proof of some additional regularity properties for the formal asymptotic solution. Assuming some restrictions on the rheological parameters, it will be proved that it is possible to gain a C^k regularity for p^* , $k > 1$, which in turn improves the regularity of u^* and the stress tensor σ^* . This result is obtained by introducing a differential Cauchy system satisfied by the derivative of p^* . Finally, section 5, is devoted to the convergence towards zero of the second term of the asymptotic expansions, which in turn proves the convergence of the solution of the real 3-D problem towards u^* , p^* , σ^* (Theorems 5.4 and 5.6).

2 Introduction of the problem and known results

2.1 Formulation of the problem

We consider unsteady incompressible flows of viscoelastic fluids, which are ruled by Oldroyd's law, in a thin domain $\hat{\Omega}^\varepsilon = \{(x, y) \in \mathbb{R}^n, x \in \omega \text{ and } 0 < y < \varepsilon h(x)\}$, where ω is an $(n - 1)$ -dimensional

domain, with $n = 2$ or $n = 3$ ($x = x_1$ or $x = (x_1, x_2)$), as in Figure 1.

Figure 1: Domain $\hat{\Omega}_\varepsilon$

The following hypotheses on h are required:

$$\forall x \in \omega, \quad 0 < h_0 \leq h(x) \leq h_M^\varepsilon, \quad \text{and} \quad h^\varepsilon \in \mathcal{C}^1(\bar{\omega}).$$

Let $\hat{\mathbf{u}}^\varepsilon = (\hat{u}_1^\varepsilon, \hat{u}_2^\varepsilon, \hat{u}_3^\varepsilon)$ be the velocity field in the three-dimensional case, or $\hat{\mathbf{u}}^\varepsilon = (\hat{u}_1^\varepsilon, \hat{u}_2^\varepsilon)$ in the two-dimensional case, \hat{p}^ε the pressure, and $\hat{\boldsymbol{\sigma}}^\varepsilon$ the stress symmetric tensor in the domain $\hat{\Omega}^\varepsilon$. Bold letters stand for vectorial or tensorial functions, the notation \hat{f} corresponds to a function f defined in the domain $\hat{\Omega}^\varepsilon$, and the superscript ε denotes the dependence on ε .

Formulation of the problem The following formulation of the problem holds in $(0, \infty) \times \hat{\Omega}^\varepsilon$:

$$\begin{cases} \rho \partial_t \hat{\mathbf{u}}^\varepsilon + \rho \hat{\mathbf{u}}^\varepsilon \cdot \nabla \hat{\mathbf{u}}^\varepsilon - (1-r)\nu \Delta \hat{\mathbf{u}}^\varepsilon + \nabla \hat{p}^\varepsilon &= \nabla \cdot \hat{\boldsymbol{\sigma}}^\varepsilon, \\ \nabla \cdot \hat{\mathbf{u}}^\varepsilon &= 0, \\ \lambda (\partial_t \hat{\boldsymbol{\sigma}}^\varepsilon + \hat{\mathbf{u}}^\varepsilon \cdot \nabla \hat{\boldsymbol{\sigma}}^\varepsilon + g(\hat{\boldsymbol{\sigma}}^\varepsilon, \nabla \hat{\mathbf{u}}^\varepsilon)) + \hat{\boldsymbol{\sigma}}^\varepsilon &= 2r\nu D(\hat{\mathbf{u}}^\varepsilon), \end{cases} \quad (2.1)$$

where the nonlinear terms $g(\hat{\boldsymbol{\sigma}}^\varepsilon, \nabla \hat{\mathbf{u}}^\varepsilon)$, the vorticity tensor $W(\hat{\mathbf{u}}^\varepsilon)$ and the deformation tensor $D(\hat{\mathbf{u}}^\varepsilon)$ are given by:

$$g(\hat{\boldsymbol{\sigma}}^\varepsilon, \nabla \hat{\mathbf{u}}^\varepsilon) = -W(\hat{\mathbf{u}}^\varepsilon) \cdot \hat{\boldsymbol{\sigma}}^\varepsilon + \hat{\boldsymbol{\sigma}}^\varepsilon \cdot W(\hat{\mathbf{u}}^\varepsilon),$$

$$W(\hat{\mathbf{u}}^\varepsilon) = \frac{\nabla \hat{\mathbf{u}}^\varepsilon - {}^t \nabla \hat{\mathbf{u}}^\varepsilon}{2} \quad \text{and} \quad D(\hat{\mathbf{u}}^\varepsilon) = \frac{\nabla \hat{\mathbf{u}}^\varepsilon + {}^t \nabla \hat{\mathbf{u}}^\varepsilon}{2}.$$

In this formulation, the physical parameters are the viscosity ν , the density ρ , and the relaxation time λ . The parameter λ is related to the viscoelastic behavior and the Deborah number. The parameter $r \in [0, 1)$ describes the relative proportion of the viscous and elastic behavior.

Initial conditions This problem is considered with the following initial conditions:

$$\hat{\mathbf{u}}^\varepsilon|_{t=0} = \hat{\mathbf{u}}_0^\varepsilon, \quad \hat{\boldsymbol{\sigma}}^\varepsilon|_{t=0} = \hat{\boldsymbol{\sigma}}_0^\varepsilon, \quad (2.2)$$

for $\hat{\mathbf{u}}_0^\varepsilon \in \mathbf{L}^2(\hat{\Omega}^\varepsilon)$, $\hat{\boldsymbol{\sigma}}_0^\varepsilon \in \mathbf{L}^2(\hat{\Omega}^\varepsilon)$. The bold notation $\mathbf{L}^2(\hat{\Omega}^\varepsilon)$ denotes the set of vectorial or tensorial functions whose all components belong to $L^2(\hat{\Omega}^\varepsilon)$.

Boundary conditions Dirichlet boundary conditions are set on top and bottom of the domain, and the conditions on the lateral part of the boundary $\hat{\Gamma}_L^\varepsilon$, defined by

$$\hat{\Gamma}_L^\varepsilon = \{(x, y) \in \mathbb{R}^n, x \in \partial\omega \text{ and } 0 < y < \varepsilon h(x)\},$$

will be specified later (in section 4.2). Therefore, it is possible to write the boundary conditions in a shortened way:

$$\hat{\mathbf{u}}^\varepsilon|_{\partial\hat{\Omega}^\varepsilon} = \hat{\mathbf{J}}^\varepsilon, \quad (2.3)$$

where $\hat{\mathbf{J}}^\varepsilon$ is a given function such that $\hat{\mathbf{J}}^\varepsilon \in \mathbf{H}^{1/2}(\partial\hat{\Omega}^\varepsilon)$ and satisfying $\hat{\mathbf{J}}^\varepsilon|_{y=h^\varepsilon} = 0$, $\hat{\mathbf{J}}^\varepsilon|_{y=0} = (s, 0)$. This function will be fully determined in Subsection 4.2.

Since $\hat{\boldsymbol{\sigma}}^\varepsilon$ satisfies a transport equation in the domain $\hat{\Omega}^\varepsilon$, it remains to impose boundary conditions on $\hat{\boldsymbol{\sigma}}^\varepsilon$ on the part of the boundary where $\hat{\mathbf{u}}^\varepsilon$ is an incoming velocity. Let us define $\hat{\Gamma}_+^\varepsilon$ the part of $\hat{\Gamma}_L^\varepsilon$ such that $\hat{\mathbf{J}}^\varepsilon|_{\hat{\Gamma}_+^\varepsilon} \cdot \mathbf{n} < 0$, and $\hat{\Gamma}_-^\varepsilon = \hat{\Gamma}_L^\varepsilon \setminus \hat{\Gamma}_+^\varepsilon$. We set

$$\hat{\boldsymbol{\sigma}}^\varepsilon|_{\hat{\Gamma}_+^\varepsilon} = \hat{\boldsymbol{\theta}}^\varepsilon, \quad (2.4)$$

where $\hat{\boldsymbol{\theta}}^\varepsilon$ is a given function in $\mathbf{H}^{1/2}(\hat{\Gamma}_+^\varepsilon)$ which will also be determined in Subsection 4.2.

Moreover, since the pressure is defined up to a constant, the mean pressure is chosen to be zero:

$$\int_{\hat{\Omega}^\varepsilon} \hat{p}^\varepsilon = 0.$$

Notations Let us introduce the following function space:

$$V = \left\{ \hat{\boldsymbol{\varphi}} \in \mathbf{H}_0^1(\hat{\Omega}^\varepsilon), \nabla \cdot \hat{\boldsymbol{\varphi}} = 0 \right\},$$

and the following notations, that will be used in the following. For \hat{f} defined in $\hat{\Omega}^\varepsilon$:

- $|\hat{f}|$ denotes the L^2 -norm in $\hat{\Omega}^\varepsilon$,
- $|\hat{f}|_p$ denotes the L^p -norm in $\hat{\Omega}^\varepsilon$, for $2 < p \leq +\infty$,
- the spaces $\mathcal{C}^m(\overline{\hat{\Omega}^\varepsilon})$ for $m \geq 1$ are equipped with the norms $\|\hat{f}\|_{\mathcal{C}^m} = |\hat{f}|_\infty + \sum_{i=1}^m |\hat{f}^{(i)}|_\infty$.

For \hat{f} defined in $\mathbb{R}^+ \times \hat{\Omega}^\varepsilon$, $\|\hat{f}\|_{L^\alpha(0, \infty, L^\beta(\hat{\Omega}^\varepsilon))}$ denotes the norm of the space $L^\alpha(0, \infty, L^\beta(\hat{\Omega}^\varepsilon))$, with $1 \leq \alpha, \beta \leq \infty$.

2.2 Existence theorem in the domain $\hat{\Omega}^\varepsilon$

Theorem 2.1. *For $\varepsilon > 0$ fixed, problem (2.1)-(2.3) admits a weak solution*

$$\hat{\mathbf{u}}^\varepsilon \in L_{loc}^2(0, \infty, \mathbf{H}^1(\hat{\Omega}^\varepsilon)), \quad \hat{p}^\varepsilon \in L_{loc}^2(0, \infty, L^2(\hat{\Omega}^\varepsilon)), \quad \hat{\boldsymbol{\sigma}}^\varepsilon \in \mathcal{C}(0, \infty, \mathbf{L}^2(\hat{\Omega}^\varepsilon)).$$

Proof. This result is proved in [13]. □

Remark 2.2. *Let us emphasize that for the following, it is essential to know the global (in time) existence of a solution for problem (2.1)-(2.3). Other existence theorems have been proved for this problem, for example in [12], [11], [10], but these theorems are either local in time (on a time interval $[0, T^\varepsilon]$), or a small data assumption is needed. In this work, these theorems cannot be used, since there is no control on the behavior of T^ε (or equivalently of the data) when ε tends to zero, in particular T^ε may tend to zero.*

Consequently, this work is restricted to the specific case treated in [13], taking one parameter of the Oldroyd model to be zero. In all generality, the non-linear term reads $g(\boldsymbol{\sigma}, \nabla \mathbf{u}) = -W(\mathbf{u}) \cdot \boldsymbol{\sigma} + \boldsymbol{\sigma} \cdot W(\mathbf{u}) - a(\boldsymbol{\sigma} \cdot D(\mathbf{u}) + D(\mathbf{u}) \cdot \boldsymbol{\sigma})$, which is called objective derivative. Here the parameter a is taken to be zero. This case corresponds to the so-called Jaumann derivative.

Remark 2.3. *The following computations are made in the two-dimensional case (i.e. $\omega = (0, L)$ is a one-dimensional domain) for the sake of simplicity. However, note that except for the regularity obtained for the limit problem in Section 4.3, all estimates are independent of the dimension, thus the corresponding computations should apply to the three-dimensional case.*

Regularizing the system In the proof of the preceding theorem, the existence of a solution is achieved by regularization. Therefore, this study only concerns solutions obtained as the limit of a regularized problem approximating (2.1), in which an additional term $-\eta \Delta \hat{\boldsymbol{\sigma}}^{\varepsilon\eta}$ is added to the Oldroyd equation, with $\eta > 0$ a small parameter. Here a regularization of the form $-\eta \Delta(\hat{\boldsymbol{\sigma}}^{\varepsilon\eta} - \hat{\mathbf{G}})$ is chosen, with $\hat{\mathbf{G}}$ a symmetric tensor in $\mathbf{H}^2(\hat{\Omega}^\varepsilon)$ independent of η and ε which will be precised later. After obtaining the needed energy estimates uniformly in η , we will let η tend to zero. This approach allows to multiply the Oldroyd equation by $\hat{\boldsymbol{\sigma}}^{\varepsilon\eta}$, since $\hat{\boldsymbol{\sigma}}^{\varepsilon\eta}$ is regular enough. Of course, one can choose another regularization which leads to energy estimates which are uniform in the regularization parameter.

Furthermore, because of the regularizing term, boundary conditions on the whole boundary are needed. Let us write $\hat{\boldsymbol{\sigma}}^{\varepsilon\eta}|_{\partial\hat{\Omega}^\varepsilon} = \hat{\boldsymbol{\theta}}^{\varepsilon\eta}$, where $\hat{\boldsymbol{\theta}}^{\varepsilon\eta}$ is now a function of $\mathbf{H}^{1/2}(\partial\hat{\Omega}^\varepsilon)$, which will be determined later by equation (4.3).

3 Asymptotic expansions

3.1 Renormalization of the domain

Introducing a new variable $z = \frac{y}{\varepsilon}$, the system (2.1) can be rewritten in a fixed re-scaled domain:

$$\Omega = \{(x, z) \in \mathbb{R}^n, x \in \omega \text{ and } 0 < z < h(x)\}.$$

For a function \hat{f} defined in Ω^ε , f is defined in Ω by $f(x, z) = \hat{f}(x, \varepsilon z)$. For a function $f \in L^p(\Omega)$, $|f|_p$ still denotes the L^p -norm in Ω , and similar notations hold for the other norms. Moreover, the regularizing term $\eta \Delta \sigma^{\varepsilon\eta}$ is introduced. Denoting $\sigma^{\varepsilon\eta} = \begin{pmatrix} \sigma_{11}^{\varepsilon\eta} & \sigma_{12}^{\varepsilon\eta} \\ \sigma_{12}^{\varepsilon\eta} & \sigma_{22}^{\varepsilon\eta} \end{pmatrix}$, and similar notations for the components of \mathbf{G} , it holds in $(0, \infty) \times \Omega$:

$$\begin{cases} \rho \delta_t u_1^{\varepsilon\eta} - (1-r)\nu \Delta_\varepsilon u_1^{\varepsilon\eta} + \partial_x p^{\varepsilon\eta} - \partial_x \sigma_{11}^{\varepsilon\eta} - \frac{1}{\varepsilon} \partial_z \sigma_{12}^{\varepsilon\eta} = 0, \\ \rho \delta_t u_2^{\varepsilon\eta} - (1-r)\nu \Delta_\varepsilon u_2^{\varepsilon\eta} + \frac{1}{\varepsilon} \partial_z p^{\varepsilon\eta} - \partial_x \sigma_{12}^{\varepsilon\eta} - \frac{1}{\varepsilon} \partial_z \sigma_{22}^{\varepsilon\eta} = 0, \\ \nabla_\varepsilon \cdot \mathbf{u}^{\varepsilon\eta} = 0, \\ \lambda \left(\delta_t \sigma_{11}^{\varepsilon\eta} - \tilde{N}(\mathbf{u}^{\varepsilon\eta}, \sigma_{12}^{\varepsilon\eta}) \right) + \sigma_{11}^{\varepsilon\eta} - \eta \Delta_\varepsilon (\sigma_{11}^{\varepsilon\eta} - G_{11}) - 2r\nu \partial_x u_1^{\varepsilon\eta} = 0, \\ \lambda \left(\delta_t \sigma_{12}^{\varepsilon\eta} + \frac{1}{2} \tilde{N}(\mathbf{u}^{\varepsilon\eta}, \sigma_{11}^{\varepsilon\eta} - \sigma_{22}^{\varepsilon\eta}) \right) + \sigma_{12}^{\varepsilon\eta} - \eta \Delta_\varepsilon (\sigma_{12}^{\varepsilon\eta} - G_{12}) - r\nu \left(\partial_x u_2^{\varepsilon\eta} + \frac{1}{\varepsilon} \partial_z u_1^{\varepsilon\eta} \right) = 0, \\ \lambda \left(\delta_t \sigma_{22}^{\varepsilon\eta} + \tilde{N}(\mathbf{u}^{\varepsilon\eta}, \sigma_{12}^{\varepsilon\eta}) \right) + \sigma_{22}^{\varepsilon\eta} - \eta \Delta_\varepsilon (\sigma_{22}^{\varepsilon\eta} - G_{22}) - 2r\nu \frac{1}{\varepsilon} \partial_z u_2^{\varepsilon\eta} = 0, \end{cases} \quad (3.1)$$

where the convective derivative δ_t is given by $\delta_t = \partial_t + \mathbf{u}^{\varepsilon\eta} \cdot \nabla_\varepsilon$. The derivation operators are defined as follows: $\nabla_\varepsilon = \left(\partial_x, \frac{1}{\varepsilon} \partial_z \right)$ and $\Delta_\varepsilon = \partial_x^2 + \frac{1}{\varepsilon^2} \partial_z^2$. The non-linear terms \tilde{N} are given by $\tilde{N}(\mathbf{u}, f) = \left(\partial_x u_2 - \frac{1}{\varepsilon} \partial_z u_1 \right) f$.

3.2 Asymptotic expansions

It has been proposed in [4] that when η, ε tend zero, $(\mathbf{u}^{\varepsilon\eta}, p^{\varepsilon\eta}, \sigma^{\varepsilon\eta})$ tends formally to a triplet $(\mathbf{u}^*, p^*, \sigma^*)$ satisfying a system that will be given later in (4.1). This analysis leads to the introduction of the following asymptotic expansions:

$$u_1^{\varepsilon\eta} = u_1^* + v_1^{\varepsilon\eta} \text{ and } u_2^{\varepsilon\eta} = \varepsilon u_2^* + \varepsilon v_2^{\varepsilon\eta}, \quad (3.2)$$

$$p^{\varepsilon\eta} = \frac{1}{\varepsilon^2} p^* + \frac{1}{\varepsilon^2} q^{\varepsilon\eta}, \quad (3.3)$$

$$\sigma^{\varepsilon\eta} = \frac{1}{\varepsilon} \sigma^* + \frac{1}{\varepsilon} \tau^{\varepsilon\eta}, \quad (3.4)$$

with $\sigma^* = \begin{pmatrix} \sigma_{11}^* & \sigma_{12}^* \\ \sigma_{12}^* & \sigma_{22}^* \end{pmatrix}$, and $\tau^{\varepsilon\eta} = \begin{pmatrix} \tau_{11}^{\varepsilon\eta} & \tau_{12}^{\varepsilon\eta} \\ \tau_{12}^{\varepsilon\eta} & \tau_{22}^{\varepsilon\eta} \end{pmatrix}$. If denoting $\mathbf{u}^* = (u_1^*, u_2^*)$, and $\mathbf{v}^{\varepsilon\eta} = (v_1^{\varepsilon\eta}, v_2^{\varepsilon\eta})$, (3.2) becomes $\mathbf{u}^{\varepsilon\eta} = \mathbf{u}^* + \mathbf{v}^{\varepsilon\eta}$.

The scaling orders chosen for the pressure and the different components of the velocity field and

of the stress tensor are motivated by some mathematical and physical remarks. Classically, the pressure has to be of order $1/\varepsilon^2$ if the horizontal velocity is of order 1 (see [2] for the rigorous explanation). On the other hand, the stress tensor has to be of order $1/\varepsilon$ and the Deborah number λ of order ε in order to balance the Newtonian and non-Newtonian contribution in Oldroyd equation (see [4]). Hence; let $\lambda = \varepsilon\lambda^*$.

A wise choice of the function \mathbf{G} in the regularizing term is $\mathbf{G} = \boldsymbol{\sigma}^*$. The regularity of \mathbf{G} in $\mathbf{H}^2(\Omega)$ is proved by Theorem 4.4 (where it is proved that $\partial_x^2 \boldsymbol{\sigma}^* \in \mathcal{C}^0(\bar{\Omega})$, $\partial_x \partial_z \boldsymbol{\sigma}^* \in \mathcal{C}^0(\bar{\Omega})$ and $\partial_z^2 \boldsymbol{\sigma}^* \in \mathcal{C}^1(\bar{\Omega})$, thus $\Delta \boldsymbol{\sigma}^* \in \mathbf{L}^2(\Omega)$). A formal substitution of (3.2), (3.3), (3.4) in (3.1) leads to the following system:

$$\left\{ \begin{array}{l} \rho \, d_t v_1^{\varepsilon\eta} - (1-r)\nu \Delta_\varepsilon v_1^{\varepsilon\eta} + \frac{1}{\varepsilon^2} \partial_x q^{\varepsilon\eta} - \frac{1}{\varepsilon} \partial_x \tau_{11}^{\varepsilon\eta} - \frac{1}{\varepsilon^2} \partial_z \tau_{12}^{\varepsilon\eta} = \tilde{L}_1^{\varepsilon\eta} + \frac{1}{\varepsilon} C_1 + \frac{1}{\varepsilon^2} C'_1, \\ \rho \, d_t v_2^{\varepsilon\eta} - (1-r)\nu \Delta_\varepsilon v_2^{\varepsilon\eta} + \frac{1}{\varepsilon^4} \partial_z q^{\varepsilon\eta} - \frac{1}{\varepsilon^2} \partial_x \tau_{12}^{\varepsilon\eta} - \frac{1}{\varepsilon^3} \partial_z \tau_{22}^{\varepsilon\eta} = \frac{1}{\varepsilon^2} \tilde{L}_2^{\varepsilon\eta} + \frac{1}{\varepsilon^3} C_2 + \frac{1}{\varepsilon^4} C'_2, \\ \nabla \cdot \mathbf{v}^{\varepsilon\eta} = \nabla \cdot \mathbf{u}^*, \\ \lambda^* \left(d_t \tau_{11}^{\varepsilon\eta} - N(\mathbf{v}^{\varepsilon\eta}, \tau_{12}^{\varepsilon\eta}) \right) + \frac{1}{\varepsilon} \tau_{11}^{\varepsilon\eta} - \eta \Delta_\varepsilon \tau_{11}^{\varepsilon\eta} - 2r\nu \partial_x v_1^{\varepsilon\eta} = \tilde{L}_{11}^{\varepsilon\eta} + \frac{1}{\varepsilon} \tilde{L}'_{11}{}^{\varepsilon\eta}, \\ \lambda^* \left(d_t \tau_{12}^{\varepsilon\eta} + \frac{1}{2} N(\mathbf{v}^{\varepsilon\eta}, \tau_{11}^{\varepsilon\eta} - \tau_{22}^{\varepsilon\eta}) \right) + \frac{1}{\varepsilon} \tau_{12}^{\varepsilon\eta} - \eta \Delta_\varepsilon \tau_{12}^{\varepsilon\eta} - r\nu \left(\partial_x v_2^{\varepsilon\eta} + \frac{1}{\varepsilon} \partial_z v_1^{\varepsilon\eta} \right) = \tilde{L}_{12}^{\varepsilon\eta} + \frac{1}{\varepsilon} \tilde{L}'_{12}{}^{\varepsilon\eta}, \\ \lambda^* \left(d_t \tau_{22}^{\varepsilon\eta} + N(\mathbf{v}^{\varepsilon\eta}, \tau_{12}^{\varepsilon\eta}) \right) + \frac{1}{\varepsilon} \tau_{22}^{\varepsilon\eta} - \eta \Delta_\varepsilon \tau_{22}^{\varepsilon\eta} - \frac{2r\nu}{\varepsilon} \partial_z v_2^{\varepsilon\eta} = \tilde{L}_{22}^{\varepsilon\eta} + \frac{1}{\varepsilon} \tilde{L}'_{22}{}^{\varepsilon\eta}, \end{array} \right. \quad (3.5)$$

with the following notations: $d_t = \partial_t + \mathbf{v}^{\varepsilon\eta} \cdot \nabla$ is the so-called convective derivative, the non-linear terms $N(\mathbf{v}^{\varepsilon\eta}, f) = \left(\varepsilon \partial_x v_2^{\varepsilon\eta} - \frac{1}{\varepsilon} \partial_z v_1^{\varepsilon\eta} \right) f$ for $f \in L^2(\Omega)$ and the following linear (with respect to $\mathbf{v}^{\varepsilon\eta}$) and constant terms

$$\begin{aligned} \tilde{L}_1^{\varepsilon\eta} &= \underbrace{-\rho \, \mathbf{v}^{\varepsilon\eta} \cdot \nabla u_1^* - \rho \, \mathbf{u}^* \cdot \nabla v_1^{\varepsilon\eta}}_{\mathcal{L}_1^{\varepsilon\eta}} - \rho \, \partial_t u_1^* - \rho \, \mathbf{u}^* \cdot \nabla u_1^* + (1-r)\nu \partial_x^2 u_1^*, \\ C_1 &= \partial_x \sigma_{11}^*, \\ C'_1 &= (1-r)\nu \partial_z^2 u_1^* - \partial_x p^* + \partial_z \sigma_{12}^*; \\ \tilde{L}_2^{\varepsilon\eta} &= \underbrace{-\rho \, \varepsilon^2 \mathbf{v}^{\varepsilon\eta} \cdot \nabla u_2^* - \rho \, \varepsilon^2 \mathbf{u}^* \cdot \nabla v_2^{\varepsilon\eta}}_{\mathcal{L}_2^{\varepsilon\eta}} \\ &\quad - \rho \, \varepsilon^2 \partial_t u_2^* - \rho \, \varepsilon^2 \mathbf{u}^* \cdot \nabla u_2^* + \varepsilon^2 (1-r)\nu \partial_x^2 u_2^* + (1-r)\nu \partial_z^2 u_2^* + \partial_x \sigma_{12}^*, \\ C_2 &= \partial_z \sigma_{22}^*, \\ C'_2 &= \partial_z p^*. \end{aligned}$$

For the Oldroyd equation, the following linear (with respect to \mathbf{v} and $\boldsymbol{\tau}$) and constant terms appear:

$$\begin{aligned} \tilde{L}_{11}^{\varepsilon\eta} &= \mathcal{L}_{11}^{\varepsilon\eta} + \lambda^* \left(-\partial_t \sigma_{11}^* - \mathbf{u}^* \cdot \nabla \sigma_{11}^* + \varepsilon \partial_x u_2^* \sigma_{12}^* \right) + 2r\nu \partial_x u_1^*, \\ \text{with } \mathcal{L}_{11}^{\varepsilon\eta} &= \lambda^* \left(\varepsilon \partial_x u_2^* \tau_{12}^{\varepsilon\eta} + \varepsilon \partial_x v_2^{\varepsilon\eta} \sigma_{12}^* - \mathbf{v}^{\varepsilon\eta} \cdot \nabla \sigma_{11}^* - \mathbf{u}^* \cdot \nabla \tau_{11}^{\varepsilon\eta} \right), \end{aligned}$$

$$\begin{aligned}
\tilde{L}'_{11} &= -\underbrace{\lambda^* (\partial_z u_1^* \tau_{12}^{\varepsilon\eta} + \partial_z v_1^* \sigma_{12}^*)}_{\mathcal{L}'_{11}{}^{\varepsilon\eta}} - \lambda^* \partial_z u_1^* \sigma_{12}^* - \sigma_{11}^*; \\
\tilde{L}_{22}^{\varepsilon\eta} &= \mathcal{L}_{22}^{\varepsilon\eta} - \lambda^* (\partial_t \sigma_{22}^* + \mathbf{u}^* \cdot \nabla \sigma_{22}^* + \varepsilon \partial_x u_2^* \sigma_{12}^*) + 2r\nu \partial_z u_2^*, \\
\text{with } \mathcal{L}_{22}^{\varepsilon\eta} &= -\lambda^* (\varepsilon \partial_x u_2^* \tau_{12}^{\varepsilon\eta} + \varepsilon \partial_x v_2^* \sigma_{12}^* + \mathbf{v}^{\varepsilon\eta} \cdot \nabla \sigma_{22}^* + \mathbf{u}^* \cdot \nabla \tau_{22}^{\varepsilon\eta}), \\
\tilde{L}'_{22} &= \underbrace{\lambda^* (\partial_z u_1^* \tau_{12}^{\varepsilon\eta} + \partial_z v_1^* \sigma_{12}^*)}_{\mathcal{L}'_{22}{}^{\varepsilon\eta}} + \lambda^* \partial_z u_1^* \sigma_{12}^* - \sigma_{22}^* \\
\tilde{L}_{12}^{\varepsilon\eta} &= -\underbrace{\frac{\lambda^*}{2} (\varepsilon \partial_x u_2^* (\tau_{11}^{\varepsilon\eta} - \tau_{22}^{\varepsilon\eta}) + \varepsilon \partial_x v_2^* (\sigma_{11}^* - \sigma_{22}^*) + 2\mathbf{v}^{\varepsilon\eta} \cdot \nabla \sigma_{12}^* + 2\mathbf{u}^* \cdot \nabla \tau_{12}^{\varepsilon\eta})}_{\mathcal{L}_{12}^{\varepsilon\eta}} \\
&\quad - \frac{\lambda^*}{2} (2\partial_t \sigma_{12}^* + 2\mathbf{u}^* \cdot \nabla \sigma_{12}^* + \partial_x u_2^* (\sigma_{11}^* - \sigma_{22}^*)) + r\nu \varepsilon \partial_x u_2^*, \\
\tilde{L}'_{12} &= -\underbrace{\frac{\lambda^*}{2} (\partial_z u_1^* (\tau_{11}^{\varepsilon\eta} - \tau_{22}^{\varepsilon\eta}) + \partial_z v_1^* (\sigma_{11}^* - \sigma_{22}^*))}_{\mathcal{L}'_{12}{}^{\varepsilon\eta}} + \frac{\lambda^*}{2} \partial_z u_1^* (\sigma_{11}^* - \sigma_{22}^*) - \sigma_{12}^* + r\nu \partial_z u_1^*;
\end{aligned}$$

Note that the first order derivatives of $\boldsymbol{\sigma}^*$ occur in the terms $\tilde{L}^{\varepsilon\eta}$ and $C^{\varepsilon\eta}$. It will be shown in Theorem 4.4 that $\boldsymbol{\sigma}^*$ has sufficient regularity.

Let us observe also that equations (3.5) are similar to (3.1), except for the linear terms on the right. Thus the energy estimates will be obtained similarly for both systems, multiplying Navier-Stokes equation by the velocity and Oldroyd equation by the stress tensor, and integrating over Ω .

4 Limit equations

4.1 Limit system

In an heuristic way, the following system of equations satisfied by \mathbf{u}^* , p^* , $\boldsymbol{\sigma}^*$ is inferred from (3.5): \mathbf{u}^* , p^* , $\boldsymbol{\sigma}^*$ are steady functions solutions of:

$$\left\{ \begin{array}{l} (1-r)\nu \partial_z^2 u_1^* - \partial_x p^* + \partial_z \sigma_{12}^* = 0, \\ \partial_z p^* = 0, \\ \nabla \cdot \mathbf{u}^* = 0, \\ \lambda^* \partial_z u_1^* \sigma_{12}^* + \sigma_{11}^* = 0, \\ -\frac{\lambda^*}{2} \partial_z u_1^* (\sigma_{11}^* - \sigma_{22}^*) + \sigma_{12}^* = r\nu \partial_z u_1^*, \\ -\lambda^* \partial_z u_1^* \sigma_{12}^* + \sigma_{22}^* = 0. \end{array} \right. \quad (4.1)$$

This system is equipped with the following boundary condition (Dirichlet condition on the upper and lower part of the boundary, flux imposed on the lateral part of the boundary):

$$\begin{cases} \mathbf{u}^* = 0, & \text{for } z = h(x), \\ \mathbf{u}^* = (s, 0), & \text{for } z = 0, \\ \int_0^{h(x)} \mathbf{u}^* dz \cdot \mathbf{n} = \Phi_0 & \text{on } \Gamma_L. \end{cases} \quad (4.2)$$

The compatibility condition reads $\int_{\partial\omega} \Phi_0 = 0$. Moreover, since p^* is defined up to a constant, the mean pressure is taken to be zero: $\int_{\Omega} p^* = 0$.

Remark 4.1. *Each equation of the preceding system (4.1) is obtained by cancelling the constant part (i.e. the part independent of $\mathbf{v}^{\varepsilon\eta}$, $q^{\varepsilon\eta}$, $\tau^{\varepsilon\eta}$) of respectively C'_1 , C'_2 , $\nabla \cdot \mathbf{u}^*$, $\tilde{L}'_{11}{}^{\varepsilon\eta}$, $\tilde{L}'_{12}{}^{\varepsilon\eta}$, $\tilde{L}'_{22}{}^{\varepsilon\eta}$.*

4.2 Determination of the boundary conditions

Remark 4.2. *The lateral boundary conditions on \mathbf{u}^* do not depend on the ones on $\mathbf{u}^{\varepsilon\eta}$, but only on the flux. Therefore, different boundary conditions on $\mathbf{u}^{\varepsilon\eta}$ corresponding to the same flux lead to the same limit problem. This is a classical fact when passing from a two-dimensional problem to a one-dimensional problem (or similarly from a three-dimensional problem to a two-dimensional one), and has already been observed in [2] for example. Here, in order to avoid boundary layers, $\mathbf{u}^{\varepsilon\eta} = \mathbf{u}^*$ is imposed on the lateral part of the boundary.*

Similarly, any value of $\boldsymbol{\sigma}^{\varepsilon\eta}$ on the boundary leads to the same limit problem. Again, in order to avoid boundary layers, well-prepared boundary conditions are also chosen for $\boldsymbol{\sigma}^{\varepsilon\eta}$.

The preceding remark allows to define precisely the function \mathbf{J}^ε introduced in (2.3). Since $\mathbf{u}^*|_{\Gamma_L} \in \mathbf{H}^{1/2}(\Gamma_L)$, it is possible to construct $\mathbf{J}^\varepsilon \in \mathbf{H}^{1/2}(\partial\Omega)$ satisfying $\mathbf{J}^\varepsilon|_{z=h} = 0$, $\mathbf{J}^\varepsilon|_{z=0} = (s, 0)$ and $\mathbf{J}^\varepsilon|_{\Gamma_L} = \mathbf{u}^*|_{\Gamma_L}$. Therefore, the boundary conditions on $\mathbf{u}^{\varepsilon\eta}$ become

$$\begin{cases} \mathbf{u}^{\varepsilon\eta} = 0, & \text{for } z = h(x), \\ \mathbf{u}^{\varepsilon\eta} = (s, 0), & \text{for } z = 0, \\ \mathbf{u}^{\varepsilon\eta} = \mathbf{u}^* & \text{on } \Gamma_L. \end{cases}$$

Thus $\mathbf{u}^{\varepsilon\eta}|_{\partial\Omega} = \mathbf{u}^*|_{\partial\Omega}$, and $\mathbf{v}^{\varepsilon\eta}$ will satisfy zero boundary conditions: $\mathbf{v}^{\varepsilon\eta}|_{\partial\Omega} = 0$.

Moreover, since $\boldsymbol{\sigma}^* \in \mathbf{H}^1(\Omega)$ (see Theorem 4.4 for this regularity result), $\boldsymbol{\theta}^\varepsilon$ can be defined as follows:

$$\boldsymbol{\theta}^\varepsilon = \boldsymbol{\sigma}^*|_{\Gamma_+} \in \mathbf{H}^{1/2}(\Gamma_+). \quad (4.3)$$

Therefore

$$\boldsymbol{\sigma}^{\varepsilon\eta}|_{\Gamma_+} = \boldsymbol{\sigma}^*|_{\Gamma_+},$$

and this implies that $\boldsymbol{\tau}^{\varepsilon\eta}|_{\Gamma_+} = 0$.

On the other part Γ_- of the boundary, $\sigma^{\varepsilon\eta}$ is chosen such that $\sigma^{\varepsilon\eta} \cdot n|_{\Gamma_-} = \sigma^* \cdot n|_{\Gamma_-}$, for example $\sigma^{\varepsilon\eta}|_{\Gamma_-} = \sigma^*|_{\Gamma_-}$.

4.3 Existence of a solution to the limit problem

System (4.1)-(4.2) has already been studied in [4].

Theorem 4.3. *Assume that $r < 8/9$. Then system (4.1)-(4.2) has a unique solution satisfying*

$$\mathbf{u}^* \in \mathbf{L}^2(\Omega), \quad \partial_z \mathbf{u}^* \in \mathbf{L}^2(\Omega), \quad p^* \in H^1(\omega), \quad \sigma^* \in \mathbf{L}^2(\Omega). \quad (4.4)$$

Proof. This result has been proved in [4]. \square

This existence result is not sufficient for this study. Therefore, the following stronger regularity result is proved on the limit problem (4.1)-(4.2).

Theorem 4.4. *Assume $r < 2/9$. If $h \in H^k(\omega)$, for $k \in \mathbb{N}^*$, then the unique solution $(\mathbf{u}^*, p^*, \sigma^*)$ of the system (4.1)-(4.2) satisfies*

$$\begin{aligned} p^* &\in \mathcal{C}^{k+1}(\bar{\omega}), \quad u_1^*, \partial_z u_1^*, \partial_z^2 u_1^* \in \mathcal{C}^{k+1}(\bar{\Omega}), \quad \sigma^*, \partial_z \sigma^* \in \mathcal{C}^{k+1}(\bar{\Omega}), \\ \partial_x u_1^* &\in \mathcal{C}^k(\bar{\Omega}), \quad u_2^*, \partial_z u_2^*, \partial_z^2 u_2^* \in \mathcal{C}^k(\bar{\Omega}), \quad \partial_x \sigma^* \in \mathcal{C}^k(\bar{\Omega}), \\ \partial_x u_2^* &\in \mathcal{C}^{k-1}(\bar{\Omega}). \end{aligned} \quad (4.5)$$

Proof. Let us observe that system (4.1) can be expressed as a system on u_1^*, p^* only. Using (4.1), $\sigma_{11}^*, \sigma_{22}^*$ can be expressed as functions of σ_{12}^* and $\partial_z u_1^*$. Indeed, from the fourth and the last equations of (4.1), it holds that

$$\sigma_{22}^* = -\sigma_{11}^* = \lambda^* \partial_z u_1^* \sigma_{12}^*. \quad (4.6)$$

Moreover, the divergence-free equation can be rewritten in order to eliminate u_2^* . Integrating this equation between $z = 0$ and $z = h$, and using the fact that $u_2^*|_{z=0} = u_2^*|_{z=h} = u_1^*|_{z=h} = 0$, it follows:

$$\partial_x \left(\int_0^h u_1^* dz \right) = 0. \quad (4.7)$$

Thus, the system in u_1^*, p^* can be written in the following form:

$$\begin{cases} -\nu(1-r)\partial_z^2 u_1^* - \partial_z \sigma_{12}^* + \partial_x p^* = 0, & \text{with } \sigma_{12}^* = \frac{\nu r \partial_z u_1^*}{1 + \lambda^{*2} |\partial_z u_1^*|^2}, \\ \partial_z p^* = 0, \\ \partial_x \left(\int_0^h u_1^* dz \right) = 0, \end{cases} \quad (4.8)$$

equipped with the boundary conditions stated in (4.2) and the condition $\int_{\Omega} p^* = 0$.

For the sake of readability, the superscripts $*$ are omitted in the rest of this section.

Denote $q = \partial_x p$. Let $\phi \in \mathcal{C}^\infty(\mathbb{R})$ defined by $\phi(t) = \nu(1-r)t + \frac{\nu r t}{1 + \lambda^2 t^2}$. The first equation of (4.8) becomes $q = \partial_z(\phi(\partial_z u_1))$.

A simple study of function ϕ allows to show the following properties:

$$0 < \nu \left(1 - \frac{9r}{8}\right) < |\phi'|_\infty < \nu, \quad \text{and} \quad \phi(t) \xrightarrow[t \rightarrow \pm\infty]{} \pm\infty. \quad (4.9)$$

Therefore the function ϕ is invertible, and $\psi = \phi^{-1}$ belongs to $\mathcal{C}^\infty(\mathbb{R})$. Moreover, ψ is an increasing function as ϕ . Integrating $q = \partial_z(\phi(\partial_z u_1))$ with respect to z between 0 and z , the first equation of (4.8) becomes:

$$\phi(\partial_z u_1(x, z)) = q(x)z + \kappa(x),$$

where $\kappa(x)$ is a integration constant. Therefore, it follows that

$$\partial_z u_1(x, z) = \psi(q(x)z + \kappa(x)).$$

Since $u_1|_{z=0} = s$, the integration between 0 and z of the preceding equation yields:

$$u_1(x, z) = s + \int_0^z \psi(q(x)t + \kappa(x)) dt. \quad (4.10)$$

The boundary condition $u_1|_{h(x)} = 0$ implies also:

$$\int_0^{h(x)} \psi(q(x)t + \kappa(x)) dt + s = 0. \quad (4.11)$$

For $(h, q, s, \kappa) \in \mathbb{R}^4$, let us introduce $F(h, q, s, \kappa) = \int_0^h \psi(qt + \kappa) dt + s$.

Lemma 4.5. *For any $(h, q, s) \in \mathbb{R}^3$ there exists a unique $\kappa \in \mathbb{R}$ such that $F(h, q, s, \kappa) = 0$.*

Proof. • If such an κ exists, it is unique from the implicit function theorem, since for all $(h, q, s, \kappa) \in \mathbb{R}^4$

$$\frac{\partial F}{\partial \kappa}(h, q, s, \kappa) = \int_0^h \psi'(qt + \kappa) dt > 0.$$

- The following limits are computed, using the fact that $\lim_{t \rightarrow \pm\infty} \psi(t) = \pm\infty$:

$$\lim_{\kappa \rightarrow +\infty} F(h, q, s, \kappa) = +\infty \quad \text{and} \quad \lim_{\kappa \rightarrow -\infty} F(h, q, s, \kappa) = -\infty.$$

Therefore, there exists $\kappa \in \mathbb{R}$ such that $F(h, q, s, \kappa) = 0$. Let us denote $K(h, q, s) = \kappa$. By the implicit function theorem, $K \in \mathcal{C}^\infty(\mathbb{R}^3)$. □

Therefore, the following expression holds for $(h, q, s) \in \mathbb{R}^3$:

$$F(h, q, s, K(h, q, s)) = 0. \quad (4.12)$$

It is now possible to obtain an information on the sign of $\partial_q K$. Indeed, deriving the expression (4.12) with respect to q , it follows

$$\partial_q F + \partial_\kappa F \partial_q K = 0.$$

For $h > 0$, since $\partial_q F = \int_0^h t \psi'(qt + \kappa) dt > 0$ and $\partial_a F = \int_0^h \psi'(qt + \kappa) dt > 0$, $\partial_q K$ is strictly negative.

Now, using equation (4.7) and the expression (4.10) for u , it follows:

$$\int_0^{h(x)} \int_0^z \partial_x \left(\psi(q(x)t + K(h(x), q(x), s)) \right) dt dz = 0.$$

or if changing the direction of integration

$$\int_0^{h(x)} (h(x) - t) \partial_x \left(\psi(q(x)t + K(h(x), q(x), s)) \right) dt = 0.$$

This can be rewritten as

$$\begin{aligned} q'(x) \int_0^{h(x)} (h(x) - t) \left((t + \partial_q K(h(x), q(x), s)) \psi'(q(x)t + K(h(x), q(x), s)) \right) dt \\ = - \int_0^{h(x)} (h(x) - t) \left(h'(x) \partial_h K(h(x), q(x), s) \right) \psi'(q(x)t + K(h(x), q(x), s)) dt, \end{aligned}$$

which can be seen as an ordinary differential equation in q . Let

$$\begin{aligned} U(x, q) &= \int_0^{h(x)} (h(x) - t) \left(t + \partial_q K(h(x), q, s) \right) \psi'(qt + K(h(x), q, s)) dt, \\ V(x, q) &= \int_0^{h(x)} (h(x) - t) \left(h'(x) \partial_h K(h(x), q, s) \right) \psi'(qt + K(h(x), q, s)) dt. \end{aligned}$$

The differential equation becomes $U(x, q(x)) q'(x) = -V(x, q(x))$ for $x \in \omega$. Note that this equation is in some sense a generalized Reynolds equation for the pressure.

Lemma 4.6. *Let $r < 2/9$. Then $U(x, q) < 0$ for any $(x, q) \in \omega \times \mathbb{R}$.*

Proof. Let $(x, q) \in \omega \times \mathbb{R}$. Equation (4.11) and the definition (4.12) of K imply:

$$\int_0^{h(x)} \psi(qt + K(h(x), q, s)) dt = -s,$$

which becomes, after derivation with respect to q

$$\int_0^{h(x)} \left(t + \partial_q K(h(x), q, s) \right) \psi'(qt + K(h(x), q, s)) dt = 0. \quad (4.13)$$

With the notation $K'(x, q) = \partial_q K(h(x), q, s)$, (4.13) implies

$$K'(x, q) = - \frac{\int_0^{h(x)} t \psi'(qt + K(h(x), q, s)) dt}{\int_0^{h(x)} \psi'(qt + K(h(x), q, s)) dt}.$$

Now, using this expression, $U(x, q)$ can be simplified:

$$U(x, q) = \int_0^{h(x)} -t \left(t + \partial_q K(h(x), q, s) \right) \psi'(qt + K(h(x), q, s)) dt. \quad (4.14)$$

Recalling the estimate of $|\phi|_\infty$ in (4.9), it follows that for any $t \in \mathbb{R}$:

$$\frac{1}{\nu} < \psi'(t) = \frac{1}{\phi'(\psi(t))} < \frac{1}{\nu(1 - 9r/8)}$$

Let $m = \frac{1}{\nu}$, $M = \frac{1}{\nu(1 - 9r/8)}$. Then

$$-\frac{bh(x)}{2m} \leq K'(x, q) \leq -\frac{ah(x)}{2M}.$$

Now, (4.14) implies that:

$$\begin{aligned} h(x)^3 \left(\frac{m}{3} - \frac{M}{4} \right) &= \int_0^{h(x)} tm \left(t - \frac{Mh(x)}{2m} \right) \\ &\leq -U(x, q) \leq \int_0^{h(x)} tM \left(t - \frac{mh(x)}{2M} \right) = h(x)^3 \left(\frac{M}{3} - \frac{m}{4} \right). \end{aligned}$$

In order to prove that U remains strictly negative, it suffices to prove that $0 < \frac{m}{3} - \frac{M}{4}$, i.e. that $\frac{m}{M} > \frac{3}{4}$, which is satisfied under the condition $r < \frac{2}{9}$. \square

It is possible to apply Picard-Lindelöf theorem (or Cauchy-Lipschitz theorem) to the ordinary differential equation $-U(x, q(x)) q'(x) = V(x, q(x))$, as U remains strictly negative by Lemma 4.6. Since ψ and K are C^∞ -functions, the regularity of q' is determined by the regularity of q and h . By hypothesis, h belongs to $H^k(\omega)$, with $k \in \mathbb{N}$, hence $h \in L^2(\omega)$. Moreover, Theorem 4.3 implies that $q \in L^2(\omega)$. Thus $q' \in L^2(\omega)$, which means $q \in H^1(\omega)$.

Iterating this process as long as h is regular, $h \in H^k(\omega)$ and $q \in H^k(\omega)$ implies that $q' \in H^k(\omega)$, thus $\partial_x p = q \in H^{k+1}(\omega)$, and $p \in H^{k+2}(\omega)$. By the classical Sobolev embedding, p belongs to $C^{k+1}(\bar{\omega})$.

Last, recalling the expression (4.10), it follows that $u_1 \in \mathcal{C}^{k+1}(\bar{\omega})$, and, taking the first and second derivatives of (4.10) with respect to z , that $\partial_z u_1, \partial_z^2 u_1$ also belong to $\mathcal{C}^{k+1}(\bar{\omega})$.

As observed in the introduction of the proof, σ and u_2 are given as functions of p, u_1 , and the needed regularity follows. \square

Remark 4.7. *Since in practical applications, h is very regular ($h \in C^\infty(\bar{\omega})$), the preceding theorem gives as much regularity as wanted. In particular, the following result will be useful subsequently.*

Corollary 4.8. *Assume $r < 2/9$. If $h \in H^1(\omega)$, then the unique solution $(\mathbf{u}^*, p^*, \sigma^*)$ of the system (4.1)-(4.2) satisfies*

$$\begin{aligned} p^* &\in \mathcal{C}^2(\bar{\omega}), \quad u_1^*, \partial_z u_1^*, \partial_z^2 u_1^* \in \mathcal{C}^2(\bar{\Omega}), \quad \sigma^*, \partial_z \sigma^* \in \mathcal{C}^2(\bar{\Omega}), \\ \partial_x u_1^* &\in \mathcal{C}^1(\bar{\Omega}), \quad u_2^*, \partial_z u_2^*, \partial_z^2 u_2^* \in \mathcal{C}^1(\bar{\Omega}), \quad \partial_x \sigma^* \in \mathcal{C}^1(\bar{\Omega}), \\ \partial_x u_2^* &\in \mathcal{C}^0(\bar{\Omega}). \end{aligned} \tag{4.15}$$

Proof. It suffices to take $k = 1$ in the preceding theorem 4.4. \square

5 Convergence of the remainders

5.1 Equations on the remainders

From now on, the superscript $\varepsilon\eta$ are dropped although the functions still depend on ε and η . Using the equations (4.1), system (3.5) becomes

$$\left\{ \begin{aligned} \rho \, d_t v_1 - (1-r)\nu \Delta_\varepsilon v_1 + \frac{1}{\varepsilon^2} \partial_x q - \frac{1}{\varepsilon} \partial_x \tau_{11} - \frac{1}{\varepsilon^2} \partial_z \tau_{12} &= L_1 + \frac{1}{\varepsilon} C_1, & (5.1a) \\ \rho \, d_t v_2 - (1-r)\nu \Delta_\varepsilon v_2 + \frac{1}{\varepsilon^4} \partial_x q - \frac{1}{\varepsilon^2} \partial_x \tau_{12} - \frac{1}{\varepsilon^3} \partial_z \tau_{22} &= \frac{1}{\varepsilon^2} L_2 + \frac{1}{\varepsilon^3} C_2, & (5.1b) \\ \nabla \cdot \mathbf{v} &= 0, & (5.1c) \\ \lambda^* d_t \tau_{11} - \lambda^* N(\mathbf{v}, \tau_{12}) + \frac{1}{\varepsilon} \tau_{11} - \eta \Delta_\varepsilon \tau_{11} - 2r\nu \partial_x v_1 &= L_{11} + \frac{1}{\varepsilon} L'_{11} + \eta \Delta_\varepsilon \sigma_{11}^*, & (5.1d) \\ \lambda^* d_t \tau_{12} + \frac{\lambda^*}{2} N(\mathbf{v}, \tau_{11} - \tau_{22}) + \frac{1}{\varepsilon} \tau_{12} - \eta \Delta_\varepsilon \tau_{12} - r\nu \left(\partial_x v_2 + \frac{1}{\varepsilon} \partial_z v_1 \right) &= L_{12} + \frac{1}{\varepsilon} L'_{12} + \eta \Delta_\varepsilon \sigma_{12}^*, & (5.1e) \\ \lambda^* d_t \tau_{22} + \lambda^* N(\mathbf{v}, \tau_{12}) + \frac{1}{\varepsilon} \tau_{22} - \eta \Delta_\varepsilon \tau_{22} - \frac{2r\nu}{\varepsilon} \partial_z v_2 &= L_{22} + \frac{1}{\varepsilon} L'_{22} + \eta \Delta_\varepsilon \sigma_{22}^*, & (5.1f) \end{aligned} \right.$$

with the new quantities

$$\begin{aligned} L_1 &= \mathcal{L}_1 - \rho \, \mathbf{u}^* \cdot \nabla u_1^* + (1-r)\nu \partial_x^2 u_1^*, \\ L_2 &= \mathcal{L}_2 - \rho \, \varepsilon^2 \mathbf{u}^* \cdot \nabla u_2^* + (1-r)\nu \partial_x^2 u_2^* + (1-r)\nu \partial_z u_2^* + \partial_x \sigma_{12}^*, \\ L_{11} &= \mathcal{L}_{11} + \lambda^* (-\mathbf{u}^* \cdot \nabla \sigma_{11}^* + \varepsilon \partial_x u_2^* \sigma_{12}^*) + 2r\nu \partial_x u_1^*, \\ L'_{11} &= \mathcal{L}'_{11}, \\ L_{12} &= \mathcal{L}_{12} - \frac{\lambda^*}{2} (2\mathbf{u}^* \cdot \nabla \sigma_{12}^* + \partial_x u_2^* (\sigma_{11}^* - \sigma_{22}^*)) + r\nu \varepsilon \partial_x u_2^*, \end{aligned}$$

$$\begin{aligned}
L'_{12} &= \mathcal{L}'_{12}, \\
L_{22} &= \mathcal{L}_{22} - \lambda^* (\mathbf{u}^* \cdot \nabla \sigma_{22}^* + \varepsilon \partial_x u_2^* \sigma_{12}^*) + 2r\nu \partial_z u_2^*, \\
L'_{22} &= \mathcal{L}'_{22}.
\end{aligned}$$

and with the initial and boundary conditions

$$\mathbf{v}|_{t=0} = \mathbf{u}_0 - \mathbf{u}^*, \quad \boldsymbol{\tau}|_{t=0} = \boldsymbol{\sigma}_0 - \boldsymbol{\sigma}^*, \quad \mathbf{v}|_{\partial\Omega} = 0, \quad \boldsymbol{\tau}|_{\Gamma_+} = 0. \quad (5.2)$$

Let us observe that both initial conditions $\mathbf{v}|_{t=0}$ and $\boldsymbol{\tau}|_{t=0}$ belong to $\mathbf{L}^2(\Omega)$. \mathbf{v} , q and $\boldsymbol{\tau}$ are defined by (3.2), (3.3), (3.4). From the existence theorem 2.1 for $(\mathbf{u}, p, \boldsymbol{\sigma})$ and theorem 4.3 for $(\mathbf{u}^*, p^*, \boldsymbol{\sigma}^*)$, it follows that system (5.1) admits a solution $(\mathbf{v}, q, \boldsymbol{\tau}) \in L^2(0, \infty, \mathbf{H}^1(\Omega)) \times L^2(0, \infty, L^2(\Omega)) \times \mathcal{C}(0, \infty, \mathbf{L}^2(\Omega))$ for $r < 8/9$.

5.2 Convergence of \mathbf{v} and $\boldsymbol{\tau}$

Before starting the a priori estimates, let us explain how the non-linear terms in (5.1) are handled. The non-linear terms $\mathbf{v} \cdot \nabla \mathbf{v}$ of Navier-Stokes equation and $\mathbf{v} \cdot \nabla \boldsymbol{\tau}$ of Oldroyd equation are treated with the following Lemma 5.1. On the other hand, the non-linear terms $N(\mathbf{v}, \boldsymbol{\tau}) = (\varepsilon \partial_x v_2 - \frac{1}{\varepsilon} \partial_z v_1) \boldsymbol{\tau}$ in (5.1d)-(5.1f) are zero when multiplied by $\boldsymbol{\tau}$.

Lemma 5.1. *Let \mathbf{n} be the exterior normal of the domain Ω . Let $\boldsymbol{\phi} \in \mathbf{H}^1(\Omega)$ be a vector field satisfying $\nabla \cdot \boldsymbol{\phi} = 0$ and $\boldsymbol{\phi} \cdot \mathbf{n}|_{\partial\Omega} = 0$. Let $w \in H^1(\Omega)$. Then*

$$\int_{\Omega} \boldsymbol{\phi} \cdot \nabla w w = 0.$$

Proof. By integration by parts:

$$\int_{\Omega} \boldsymbol{\phi} \cdot \nabla w w = - \int_{\Omega} \underbrace{\nabla \cdot \boldsymbol{\phi}}_{=0} w^2 - \int_{\Omega} \boldsymbol{\phi} \cdot \nabla w w + \int_{\partial\Omega} \underbrace{\boldsymbol{\phi} \cdot \mathbf{n}}_{=0} w^2 = 0.$$

□

The classical approach consists in obtaining a priori estimates for \mathbf{v} .

Proposition 5.2. *Let $(\mathbf{v}, q, \boldsymbol{\tau})$ be a solution of (5.1). Then $\mathbf{v} = (v_1, v_2)$ satisfy the following inequality for ε small enough:*

$$r\nu\rho \frac{d}{dt} (|v_1|^2 + |\varepsilon v_2|^2) + \frac{3}{2}r(1-r)\nu^2 (|\nabla_{\varepsilon} v_1|^2 + |\varepsilon \nabla_{\varepsilon} v_2|^2) \leq -\mathcal{D}_1 - \mathcal{D}_2 + C, \quad (5.3)$$

where $\mathcal{D}_1 = \frac{2r\nu}{\varepsilon} \int_{\Omega} \tau_{11} \partial_x v_1 + \frac{2r\nu}{\varepsilon^2} \int_{\Omega} \tau_{12} \partial_z v_1$, $\mathcal{D}_2 = 2r\nu \int_{\Omega} \tau_{12} \partial_x v_2 + \frac{2r\nu}{\varepsilon} \int_{\Omega} \tau_{22} \partial_z v_2$ and C is a constant independent of ε .

Proof. The proof consists in obtaining classical a priori estimates on both v_1 and v_2 .

Step 1. Let us multiply (5.1a) by v_1 and integrate over Ω . Observe that v_1 is regular enough to do so. Since $\mathbf{v}|_{\partial\Omega} = 0$, the boundary terms in the integration by parts are all zero. For example $-\int_{\Omega} \Delta_{\varepsilon} v_1 v_1 = \int_{\Omega} |\nabla_{\varepsilon} v_1|^2$. Moreover, the convection terms $\int_{\Omega} \mathbf{v} \cdot \nabla v_1 v_1$ contained in $\int_{\Omega} d_t v_1 v_1$ are equal to zero by Lemma 5.1, since $\nabla \cdot \mathbf{v} = 0$ and $\mathbf{v}|_{\partial\Omega} = 0$. It follows:

$$\frac{\rho}{2} \frac{d}{dt} |v_1|^2 + (1-r)\nu |\nabla_{\varepsilon} v_1|^2 - \frac{1}{\varepsilon^2} \int_{\Omega} q \partial_x v_1 = \underbrace{-\frac{1}{\varepsilon} \int_{\Omega} \tau_{11} \partial_x v_1 - \frac{1}{\varepsilon^2} \int_{\Omega} \tau_{12} \partial_z v_1}_{-\mathcal{D}_1/2r\nu} + \int_{\Omega} L_1 v_1 + \frac{1}{\varepsilon} \int_{\Omega} C_1 v_1. \quad (5.4)$$

It remains to estimate the terms $\int_{\Omega} L_1 v_1$ and $\int_{\Omega} C_1 v_1$.

Main idea Estimates of the form: $\int_{\Omega} L_1 v_1 + \frac{1}{\varepsilon} \int_{\Omega} C_1 v_1 \leq C + \kappa_1 |\nabla_{\varepsilon} v_1|^2 + \kappa_2 |\partial_z v_2|^2$ will be proved, where C is a constant independent of ε and where the constants κ_1, κ_2 satisfy $\kappa_1, \kappa_2 < (1-r)\nu/4$. These constants will be precised later in the proof.

In the following, C , c_i and M_i will denote some constants independent of ε and η , which might depend on $|\Omega|$, on the physical parameters of the problem and on \mathbf{u}^* , $\boldsymbol{\sigma}^*$ in sufficiently regular norms.

- Let us estimate first the linear (with respect to \mathbf{v}) term \mathcal{L}_1 of L_1 . To this end, Poincar inequality is useful: for $f \in L^2(\Omega)$, with $f|_{z=h} = 0$, $|f| \leq C_P |\partial_z f|$. The constant C_P only depends on Ω .

$$\star \quad \rho \int_{\Omega} v_1 \partial_x u_1^* v_1 \leq \rho |\partial_x u_1^*|_{\infty} |v_1|^2 \leq \rho \varepsilon^2 C_P^2 |\partial_x u_1^*|_{\infty} \left| \frac{1}{\varepsilon} \partial_z v_1 \right|^2 =: M_1 \varepsilon^2 \left| \frac{1}{\varepsilon} \partial_z v_1 \right|^2.$$

Note that by Theorem 4.4, $\partial_x u_1^* \in L^{\infty}(\Omega)$. In the following, all the regularity results used in the estimates also follow from Theorem 4.4.

- ★ For the next term, Poincar inequality is combined with Young inequality:

$$\begin{aligned} \rho \int_{\Omega} v_2 \partial_z u_1^* v_1 &\leq \rho |\partial_z u_1^*|_{\infty} |v_2| |v_1| \leq \rho C_P^2 |\partial_z u_1^*|_{\infty} |\partial_z v_2| |\partial_z v_1| \\ &\leq \underbrace{\rho C_P^2 |\partial_z u_1^*|_{\infty}}_{=: M_2} \left(\frac{\varepsilon}{2} |\partial_z v_2|^2 + \frac{\varepsilon}{2} \left| \frac{1}{\varepsilon} \partial_z v_1 \right|^2 \right). \end{aligned}$$

- ★ In a similar way:

$$\rho \int_{\Omega} \mathbf{u}^* \cdot \nabla v_1 v_1 \leq \underbrace{\rho C_P |u_1^*|_{\infty}}_{=: M_3} \left(\frac{\varepsilon}{2} |\partial_x v_1|^2 + \frac{\varepsilon}{2} \left| \frac{1}{\varepsilon} \partial_z v_1 \right|^2 \right) + \varepsilon^2 \underbrace{\rho C_P |u_2^*|_{\infty}}_{=: M_4} \left| \frac{1}{\varepsilon} \partial_z v_1 \right|^2.$$

Observe here that it was not possible to apply Lemma 5.1, since $\mathbf{u}^* \cdot \mathbf{n}|_{\partial\Omega} \neq 0$.

- It remains the easier terms of L_1 and C_1 (the ones which do not depend on \mathbf{v}).

★ The first term is treated using again Poincar and Young inequalities:

$$\rho \int_{\Omega} \mathbf{u}^* \cdot \nabla u_1^* v_1 \leq \rho C_P |\mathbf{u}^*|_{\infty} |\nabla u_1^*| |\partial_z v_1| \leq \frac{1}{2} (\rho C_P |\mathbf{u}^*|_{\infty} |\nabla u_1^*|)^2 + \frac{\varepsilon^2}{2} \left| \frac{1}{\varepsilon} \partial_z v_1 \right|^2 \leq C + \frac{\varepsilon^2}{2} \left| \frac{1}{\varepsilon} \partial_z v_1 \right|^2.$$

★ Similarly, $(1-r)\nu \int_{\Omega} \partial_x^2 u_1^* v_1 \leq C + \frac{\varepsilon^2}{2} \left| \frac{1}{\varepsilon} \partial_z v_1 \right|^2.$

★ The last term is estimated as follows, using Young inequality:

$$\frac{1}{\varepsilon} \int_{\Omega} \partial_x \sigma_{11}^* v_1 \leq \frac{1}{4c} |\partial_x \sigma_{11}^*|^2 + c \left| \frac{1}{\varepsilon} \partial_z v_1 \right|^2 \leq C + c \left| \frac{1}{\varepsilon} \partial_z v_1 \right|^2,$$

where c is a positive constant independent of ε that can be chosen arbitrarily.

Now, let us choose ε and c small enough such that all constants satisfy:

$$M_1 \varepsilon^2, \frac{M_2 \varepsilon}{2}, \frac{M_3 \varepsilon}{2}, M_4 \varepsilon^2, \frac{\varepsilon^2}{2}, c \leq \frac{(1-r)\nu}{36}. \quad (5.5)$$

Step 2. Let us multiply (5.1b) by $\varepsilon^2 v_2$ and integrate over Ω . Again, the boundary terms in the integrations by parts vanish, since $v_2|_{\partial\Omega} = 0$, and the convection terms are equal to zero since $\nabla \cdot \mathbf{v} = 0$ and $\mathbf{v}|_{\partial\Omega} = 0$ (by Lemma 5.1). It follows:

$$\frac{\rho \varepsilon^2}{2} \frac{d}{dt} |v_2|^2 + (1-r)\nu |\varepsilon \nabla_{\varepsilon} v_2|^2 - \frac{1}{\varepsilon^2} \int_{\Omega} q \partial_z v_2 = \underbrace{- \int_{\Omega} \tau_{12} \partial_x v_2 - \frac{1}{\varepsilon} \int_{\Omega} \tau_{22} \partial_z v_2}_{-\mathcal{D}_2/2r\nu} + \int_{\Omega} L_2 v_2 + \frac{1}{\varepsilon} \int_{\Omega} C_2 v_2. \quad (5.6)$$

Each term of $\int_{\Omega} L_2 v_2$ and $\int_{\Omega} C_2 v_2$ is estimated with the help of Poincar and Young inequalities as in the preceding step.

$$\star \varepsilon^2 \rho \int_{\Omega} \mathbf{v} \cdot \nabla u_2^* v_2 \leq \varepsilon^2 \underbrace{\rho C_P^2 |\partial_x u_2^*|_{\infty}}_{=:M_5} \left(\frac{\varepsilon}{2} \left| \frac{1}{\varepsilon} \partial_z v_1 \right|^2 + \frac{\varepsilon}{2} |\partial_z v_2|^2 \right) + \varepsilon^2 \underbrace{\rho C_P^2 |\partial_z u_2^*|_{\infty}}_{=:M_6} |\partial_z v_2|^2.$$

$$\star \varepsilon^2 \rho \int_{\Omega} \mathbf{u}^* \cdot \nabla v_2 v_2 \leq \varepsilon \underbrace{\rho C_P |u_1^*|_{\infty}}_{=:M_7} (|\varepsilon \partial_x v_2|^2 + |\partial_z v_2|^2) + \varepsilon^2 \underbrace{\rho C_P |u_2^*|_{\infty}}_{=:M_8} |\partial_z v_2|^2.$$

$$\star \varepsilon^2 \rho \int_{\Omega} \mathbf{u}^* \cdot \nabla u_2^* v_2 \leq \frac{1}{2} \varepsilon^2 \rho |\mathbf{u}^*|_{\infty}^2 |\nabla u_2^*|^2 + \varepsilon^2 \underbrace{\frac{1}{2} C_P^2}_{=:M_9} |\partial_z v_2|^2 \leq C + \varepsilon^2 M_9 |\partial_z v_2|^2.$$

★ By integration by parts (all boundary terms are equal to zero since $v_2|_{\partial\Omega} = 0$) and Young inequality as before:

$$(1-r)\nu \varepsilon^2 \int_{\Omega} \partial_x^2 u_2^* v_2 = -(1-r)\nu \varepsilon^2 \int_{\Omega} \partial_x u_2^* \partial_x v_2 \leq \varepsilon \underbrace{(1-r)\nu}_{=:M_{10}} \left(\frac{1}{2} |\partial_x u_2^*|^2 + \frac{1}{2} |\varepsilon \partial_x v_2|^2 \right).$$

★ $(1-r)\nu \int_{\Omega} \partial_z^2 u_2^* r_2 \leq \frac{1}{4c_1}(1-r)^2\nu^2 C_P^2 |\partial_z^2 u_2^*|^2 + c_1 |\partial_z v_2|^2 \leq C + c_1 |\partial_z v_2|^2$, where c_1 is a arbitrary positive constant.

★ $\int_{\Omega} \partial_x \sigma_{12}^* v_2 \leq \frac{C_P^2}{4c_1} |\partial_x \sigma_{12}^*|^2 + c_1 |\partial_z v_2|^2 \leq C + c_1 |\partial_z v_2|^2$.

★ The C_2 term is treated with integration by parts (again, no boundary terms since $v_2|_{\partial\Omega} = v_1|_{\partial\Omega} = 0$) and the divergence equation. The term is then treated as the preceding one:

$$\begin{aligned} \frac{1}{\varepsilon} \int_{\Omega} \partial_z \sigma_{22}^* v_2 &= -\frac{1}{\varepsilon} \int_{\Omega} \sigma_{22}^* \partial_z v_2 = \frac{1}{\varepsilon} \int_{\Omega} \sigma_{22}^* \partial_x v_1 = -\frac{1}{\varepsilon} \int_{\Omega} \partial_x \sigma_{22}^* v_1 \\ &\leq C_P |\partial_x \sigma_{22}^*| \left| \frac{1}{\varepsilon} \partial_z v_1 \right| \leq \frac{C_P^2}{4c_2} |\partial_x \sigma_{22}^*|^2 + c_2 \left| \frac{1}{\varepsilon} \partial_z v_1 \right|^2 \leq C + c_2 \left| \frac{1}{\varepsilon} \partial_z v_1 \right|^2. \end{aligned}$$

Now, let us choose ε , c_1 and c_2 small enough such that

$$\frac{M_5 \varepsilon^3}{2}, M_6 \varepsilon^2, M_7 \varepsilon, M_8 \varepsilon, M_9 \varepsilon, \frac{M_{10} \varepsilon}{2}, c_1, c_2 \leq \frac{(1-r)\nu}{36}. \quad (5.7)$$

Step 3. After summing (5.4) and (5.6), and multiplying by $2r\nu$, it holds for ε small enough (satisfying (5.5) and (5.7)):

$$r\nu\rho \frac{d}{dt} (|v_1|^2 + |\varepsilon v_2|^2) + \frac{3}{2}r(1-r)\nu^2 (|\nabla_{\varepsilon} v_1|^2 + |\varepsilon \nabla_{\varepsilon} v_2|^2) - \frac{2r\nu}{\varepsilon^2} \int_{\Omega} q (\partial_x v_1 + \partial_z v_2) \leq -\mathcal{D}_1 - \mathcal{D}_2 + C,$$

where C is a constant independent of ε . From the divergence equation $\nabla \cdot \mathbf{v} = \partial_x v_1 + \partial_z v_2 = 0$ it follows that the pressure term $\int_{\Omega} q (\partial_x v_1 + \partial_z v_2) = 0$, and equation (5.3) is obtained. \square

Proposition 5.3. *Let us suppose that*

$$\lambda^* |\partial_z u_1^*|_{\infty} \leq 1/12, \quad \lambda^* |\sigma_{12}^*|_{\infty} \leq \chi, \quad \lambda^* (|\sigma_{11}^*|_{\infty} + |\sigma_{22}^*|_{\infty}) \leq \chi, \quad 2\lambda^* |\partial_z \sigma_{12}^*|_{\infty} \leq \chi, \quad \lambda^* |\partial_z \sigma_{11}^*|_{\infty} \leq \chi,$$

where $\chi = \frac{\nu}{6} \sqrt{r(1-r)}$. Then for ε small enough, τ_{11} , τ_{12} , τ_{22} solution of (5.1) satisfy the following inequality:

$$\begin{aligned} \frac{\lambda^*}{2\varepsilon} \frac{d}{dt} (|\tau_{11}|^2 + 2|\tau_{12}|^2 + |\tau_{22}|^2) + \frac{1}{2} \left(\left| \frac{1}{\varepsilon} \tau_{11} \right|^2 + 2 \left| \frac{1}{\varepsilon} \tau_{12} \right|^2 + \left| \frac{1}{\varepsilon} \tau_{22} \right|^2 \right) \\ + \frac{\eta}{\varepsilon} (|\nabla_{\varepsilon} \tau_{11}|^2 + 2|\nabla_{\varepsilon} \tau_{12}|^2 + |\nabla_{\varepsilon} \tau_{22}|^2) \leq \mathcal{D}_1 + \mathcal{D}_2 + r(1-r)\nu^2 (|\nabla_{\varepsilon} v_1|^2 + |\varepsilon \nabla_{\varepsilon} v_2|^2) + C, \end{aligned} \quad (5.8)$$

where C is a constant independent of ε .

Proof. As in the preceding proposition, classical a priori estimates on τ_{11} , τ_{12} and τ_{22} are obtained, and the remaining terms are estimated accurately.

Step 1. Let us multiply (5.1d) by $\frac{\tau_{11}}{\varepsilon}$ and integrate over Ω . Again, the convection terms $\int_{\Omega} \mathbf{v} \cdot \nabla \tau_{11} \tau_{11}$ contained in $\int_{\Omega} d_t \tau_{11} \tau_{11}$ are equal to zero by Lemma 5.1, since $\nabla \cdot \mathbf{v} = 0$ and $\mathbf{v}|_{\partial\Omega} = 0$ (see (5.2)). Moreover, there is no boundary term in the integration by parts since the boundary conditions on σ have been chosen such that $\boldsymbol{\tau} \cdot \mathbf{n}|_{\partial\Omega} = 0$ (see also (5.2)). It follows:

$$\begin{aligned} \frac{\lambda^*}{2\varepsilon} \frac{d}{dt} |\tau_{11}|^2 - \frac{\lambda^*}{\varepsilon} \int_{\Omega} N(\mathbf{v}, \tau_{12}) \tau_{11} + \left| \frac{1}{\varepsilon} \tau_{11} \right|^2 + \frac{\eta}{\varepsilon} |\nabla_{\varepsilon} \tau_{11}|^2 \\ = \frac{2r\nu}{\varepsilon} \int_{\Omega} \partial_x v_1 \tau_{11} + \frac{1}{\varepsilon} \int_{\Omega} L_{11} \tau_{11} + \frac{1}{\varepsilon^2} \int_{\Omega} L'_{11} \tau_{11}. \end{aligned} \quad (5.9)$$

- The terms of $\int_{\Omega} \mathcal{L}_{11} \tau_{11}$ are estimated as follows:

$$\star \quad \lambda^* \int_{\Omega} \partial_x u_2^* \tau_{12} \tau_{11} \leq \underbrace{\lambda^* |\partial_x u_2^*|_{\infty}}_{=: M_{11}} \left(\frac{\varepsilon^2}{2} \left| \frac{1}{\varepsilon} \tau_{11} \right|^2 + \frac{\varepsilon^2}{2} \left| \frac{1}{\varepsilon} \tau_{12} \right|^2 \right).$$

$$\star \quad \text{In a same way: } \frac{\lambda^*}{\varepsilon} \int_{\Omega} v_1 \partial_x \sigma_{11}^* \tau_{11} \leq \underbrace{\lambda^* |\partial_x \sigma_{11}^*|_{\infty} C_P}_{=: M_{12}} \left(\frac{\varepsilon}{2} \left| \frac{1}{\varepsilon} \partial_z v_1 \right|^2 + \frac{\varepsilon}{2} \left| \frac{1}{\varepsilon} \tau_{11} \right|^2 \right).$$

Let us choose ε small enough such that:

$$\frac{M_{11}\varepsilon^2}{2} \leq \frac{1}{24} \quad \text{and} \quad \frac{M_{12}\varepsilon}{2} \leq \text{Min} \left\{ \frac{r(1-r)\nu}{6}, \frac{1}{24} \right\}.$$

$$\star \quad \lambda^* \int_{\Omega} \partial_x v_2 \sigma_{12}^* \tau_{11} \leq \lambda^* |\sigma_{12}^*|_{\infty} |\varepsilon \partial_x v_2| \left| \frac{1}{\varepsilon} \tau_{11} \right| \leq \lambda^* |\sigma_{12}^*|_{\infty} \left(\frac{1}{4c_3} |\varepsilon \partial_x v_2|^2 + c_3 \left| \frac{1}{\varepsilon} \tau_{11} \right|^2 \right).$$

Here, it is not possible to choose c_3 such that both coefficients are less than $r(1-r)\nu/6$ and $1/24$. Therefore, a condition on $\lambda^* |\sigma_{12}^*|_{\infty}$ is imposed such that:

$$\frac{\lambda^* |\sigma_{12}^*|_{\infty}}{4c_3} \leq \frac{r(1-r)\nu}{6} \quad \text{and} \quad \lambda^* |\sigma_{12}^*|_{\infty} c_3 \leq \frac{1}{24}.$$

Choosing c_3 satisfying $\lambda^* |\sigma_{12}^*|_{\infty} c_3 = 1/24$, the condition on $\lambda^* |\sigma_{12}^*|_{\infty}$ becomes:

$$\lambda^* |\sigma_{12}^*|_{\infty} \leq \frac{\nu}{6} \sqrt{r(1-r)} =: \chi.$$

- Similarly the following term can be estimated:

$$\frac{\lambda^*}{\varepsilon} \int_{\Omega} v_2 \partial_z \sigma_{11}^* \tau_{11} \leq \lambda^* |\partial_z \sigma_{11}^*|_{\infty} |\partial_z v_2| \left| \frac{1}{\varepsilon} \tau_{11} \right| \leq \lambda^* |\partial_z \sigma_{11}^*|_{\infty} \left(\frac{1}{4c_3} |\partial_z v_2|^2 + c_3 \left| \frac{1}{\varepsilon} \tau_{11} \right|^2 \right).$$

The same reasoning as before allows to control both terms providing that $\lambda^* |\partial_z \sigma_{11}^*|_{\infty} \leq \chi$.

- In order to treat the term $-\lambda^* \int_{\Omega} \mathbf{u}^* \cdot \nabla \tau_{11} \tau_{11}$, it is not possible to apply Lemma 5.1, since

$\mathbf{u}^* \cdot n|_{\partial\Omega} \neq 0$. However, integration by parts implies that

$$-\lambda^* \int_{\Omega} \mathbf{u}^* \cdot \nabla \tau_{11} \tau_{11} = -\frac{\lambda^*}{2} \int_{\partial\Omega} \mathbf{u}^* \cdot n \tau_{11}^2.$$

On ω , since $\mathbf{u}^* = (s, 0)$ (see (4.2)), it holds $\mathbf{u}^* \cdot n = 0$. Thus it remains to consider the boundary integral on Γ_L . This boundary integral is split into two integrals on Γ_+ and Γ_- . On Γ_- , it holds $\mathbf{u}^* \cdot n > 0$, thus $-\frac{\lambda^*}{2} \int_{\Gamma_-} \mathbf{u}^* \cdot n \tau_{11}^2 \leq 0$, and this term is trivially bounded by zero.

On Γ_+ , the boundary conditions are chosen in subsection 4.2 such that $\boldsymbol{\tau}|_{\Gamma_+} = 0$, therefore $-\frac{\lambda^*}{2} \int_{\Gamma_+} \mathbf{u}^* \cdot n \tau_{11}^2 = 0$.

- All other terms of $\int_{\Omega} L_{11} \tau_{11}$ are easier to manage, since they are linear in τ_{11} , and they are treated with Young and Poincar inequalities in a same way as the ones in v_1, v_2 .
- For the terms of $\int_{\Omega} L'_{11} \tau_{11}$, we proceed as before:

$$\frac{\lambda^*}{\varepsilon^2} \int_{\Omega} \partial_z u_1^* \tau_{12} \tau_{11} \leq \lambda^* |\partial_z u_1^*|_{\infty} \left| \frac{1}{\varepsilon} \tau_{12} \right| \left| \frac{1}{\varepsilon} \tau_{11} \right| \leq \lambda^* |\partial_z u_1^*|_{\infty} \left(\frac{1}{2} \left| \frac{1}{\varepsilon} \tau_{12} \right|^2 + \frac{1}{2} \left| \frac{1}{\varepsilon} \tau_{11} \right|^2 \right).$$

Choosing $\lambda^* |\partial_z u_1^*|_{\infty} \leq 1/12$, both terms are bounded by $1/24$.

$$\frac{\lambda^*}{\varepsilon^2} \int_{\Omega} \partial_z v_1 \sigma_{12}^* \tau_{11} \leq \lambda^* |\sigma_{12}^*|_{\infty} \left| \frac{1}{\varepsilon} \partial_z v_1 \right| \left| \frac{1}{\varepsilon} \tau_{11} \right| \leq \lambda^* |\sigma_{12}^*|_{\infty} \left(\frac{1}{4c_3} \left| \frac{1}{\varepsilon} \partial_z v_1 \right|^2 + c_3 \left| \frac{1}{\varepsilon} \tau_{11} \right|^2 \right).$$

Imposing $\lambda^* |\sigma_{12}^*|_{\infty} \leq \chi$ is enough to ensure that the coefficients are less than $r(1-r)\nu/6$ and $1/24$.

Step 2. Now, multiplying equation (5.1e) by $\frac{2\tau_{12}}{\varepsilon}$ and integrating over Ω , with the same reasoning as in the preceding step it follows:

$$\begin{aligned} \frac{\lambda^*}{\varepsilon} \frac{d}{dt} |\tau_{12}|^2 + \frac{\lambda^*}{\varepsilon} \int_{\Omega} N(\mathbf{v}, \tau_{11} - \tau_{22}) \tau_{12} + 2 \left| \frac{1}{\varepsilon} \tau_{12} \right|^2 + \frac{2\eta}{\varepsilon} |\nabla_{\varepsilon} \tau_{12}|^2 \\ = \frac{2r\nu}{\varepsilon} \int_{\Omega} \left(\partial_x v_2 + \frac{1}{\varepsilon} \partial_z v_1 \right) \tau_{12} + \frac{2}{\varepsilon} \int_{\Omega} L_{12} \tau_{12} + \frac{2}{\varepsilon^2} \int_{\Omega} L'_{12} \tau_{12} \end{aligned} \quad (5.10)$$

The terms in L_{12} and L'_{12} are of the same type as the ones in L_{11} and L'_{11} , and are treated very similarly to them, applying Young inequality, and assuming smallness assumptions on ε . Thus, let us only write the terms needing additional assumptions.

$$\star \lambda^* \int_{\Omega} \partial_x v_2 (\sigma_{11}^* - \sigma_{22}^*) \tau_{12} \leq \lambda^* (|\sigma_{11}^*|_{\infty} + |\sigma_{22}^*|_{\infty}) |\varepsilon \partial_x v_2| \left| \frac{1}{\varepsilon} \tau_{12} \right|, \text{ and it is enough to assume that } \lambda^* (|\sigma_{11}^*|_{\infty} + |\sigma_{22}^*|_{\infty}) \leq \chi.$$

$\star \frac{2\lambda^*}{\varepsilon} \int_{\Omega} v_2 \partial_z \sigma_{12}^* \tau_{12} \leq 2\lambda^* |\partial_z \sigma_{12}^*|_{\infty} |\partial_z v_2| \left| \frac{1}{\varepsilon} \tau_{12} \right|$, and we assume that $2\lambda^* |\partial_z \sigma_{12}^*|_{\infty} \leq \chi$.
 $\star \frac{\lambda^*}{\varepsilon^2} \int_{\Omega} \partial_z u^* (\tau_{11} - \tau_{22}) \tau_{12} \leq \lambda^* |\partial_z u_1^*|_{\infty} \left(\left| \frac{1}{\varepsilon} \tau_{11} \right| + \left| \frac{1}{\varepsilon} \tau_{22} \right| \right) \left| \frac{1}{\varepsilon} \tau_{12} \right|$, it has already been assumed that $\lambda^* |\partial_z u_1^*|_{\infty} \leq 1/12$.
 $\star \frac{\lambda^*}{\varepsilon^2} \int_{\Omega} \partial_z v_1 (\sigma_{11}^* - \sigma_{22}^*) \tau_{12} \leq \lambda^* (|\sigma_{11}^*|_{\infty} + |\sigma_{22}^*|_{\infty}) \left| \frac{1}{\varepsilon} \partial_z v_1 \right| \left| \frac{1}{\varepsilon} \tau_{12} \right|$, it has already been assumed that $\lambda^* (|\sigma_{11}^*|_{\infty} + |\sigma_{22}^*|_{\infty}) \leq \chi$.

Step 3. Multiplying (5.1f) by $\frac{\tau_{22}}{\varepsilon}$, and estimating the terms just as the ones in τ_{11} , it follows

$$\begin{aligned}
& \frac{\lambda^*}{2\varepsilon} \frac{d}{dt} |\tau_{22}|^2 + \frac{\lambda^*}{\varepsilon} \int_{\Omega} N(\mathbf{v}, \tau_{12}) \tau_{22} + \left| \frac{1}{\varepsilon} \tau_{22} \right|^2 + \frac{\eta}{\varepsilon} |\nabla_{\varepsilon} \tau_{22}|^2 \\
& = \frac{2r\nu}{\varepsilon^2} \int_{\Omega} \partial_z v_2 c + \frac{1}{\varepsilon} \int_{\Omega} L_{22} \tau_{22} + \frac{1}{\varepsilon^2} \int_{\Omega} L'_{22} \tau_{22}.
\end{aligned} \tag{5.11}$$

Assuming that $\lambda |\sigma_{12}^*|_{\infty} \leq \chi$, $\lambda^* |\partial_z \sigma_{11}^*|_{\infty} \leq \chi$ and $\lambda^* |\partial_z u_1^*|_{\infty} \leq 1/12$, all the terms $\frac{1}{\varepsilon} \int_{\Omega} L_{22} \tau_{22}$ and $\frac{1}{\varepsilon^2} \int_{\Omega} L'_{22} \tau_{22}$ are bounded and estimated as in Step 1.

Step 4. Summing (5.9), (5.10) and (5.11), and noticing that

$$\begin{aligned}
& - \int_{\Omega} N(\mathbf{v}, \tau_{12}) \tau_{11} + \int_{\Omega} N(\mathbf{v}, \tau_{11} - \tau_{22}) \tau_{12} + \int_{\Omega} N(\mathbf{v}, \tau_{12}) \tau_{22} \\
& = \int_{\Omega} \left(\varepsilon \partial_x v_2 - \frac{1}{\varepsilon} \partial_z v_1 \right) (-\tau_{12} \tau_{11} + (\tau_{11} - \tau_{22}) \tau_{12} + \tau_{12} \tau_{22}) = 0,
\end{aligned}$$

it follows that for ε small enough

$$\begin{aligned}
& \frac{\lambda^*}{2\varepsilon} \frac{d}{dt} (|\tau_{11}|^2 + 2|\tau_{12}|^2 + |\tau_{22}|^2) + \frac{1}{2} \left(\left| \frac{1}{\varepsilon} \tau_{11} \right|^2 + 2 \left| \frac{1}{\varepsilon} \tau_{12} \right|^2 + \left| \frac{1}{\varepsilon} \tau_{22} \right|^2 \right) + \frac{\eta}{\varepsilon} (|\nabla_{\varepsilon} \tau_{11}|^2 + 2|\nabla_{\varepsilon} \tau_{12}|^2 + |\nabla_{\varepsilon} \tau_{22}|^2) \\
& \leq \mathcal{D}_1 + \mathcal{D}_2 + r(1-r)\nu^2 (|\nabla_{\varepsilon} v_1|^2 + |\varepsilon \nabla_{\varepsilon} v_2|^2) + C,
\end{aligned}$$

where we recognized the terms $\mathcal{D}_1 + \mathcal{D}_2$, and where C is a constant independent of ε . □

From now on, let us come back to the notation with the superscripts $^{\varepsilon\eta}$, denoting the dependence on ε and η .

Theorem 5.4. *Suppose that the solution \mathbf{u}^*, σ^* of system (4.1)-(4.2) satisfies the following small-*

ness assumptions

$$\lambda^* |\partial_z u_1^*|_\infty \leq 1/12, \quad \lambda^* |\sigma_{12}^*|_\infty \leq \chi, \quad \lambda^* (|\sigma_{11}^*|_\infty + |\sigma_{22}^*|_\infty) \leq \chi, \quad 2\lambda^* |\partial_z \sigma_{12}^*|_\infty \leq \chi, \quad \lambda^* |\partial_z \sigma_{11}^*|_\infty \leq \chi, \quad (5.12)$$

where $\chi = \frac{\nu}{6} \sqrt{r(1-r)}$. Then the following convergences hold up to subsequences when η and then ε tend to zero:

$$u_1^{\varepsilon\eta} \rightharpoonup u_1^*, \quad \partial_z u_1^{\varepsilon\eta} \rightharpoonup \partial_z u_1^*, \quad \partial_x u_1^{\varepsilon\eta} \rightharpoonup \partial_x u_1^* \quad \text{in } L^2(0, T, L^2(\Omega)), \quad (5.13)$$

$$u_2^{\varepsilon\eta} \rightarrow 0, \quad \partial_z u_2^{\varepsilon\eta} \rightarrow 0, \quad \partial_x u_2^{\varepsilon\eta} \rightarrow 0 \quad \text{in } L^2(0, T, L^2(\Omega)), \quad (5.14)$$

$$\varepsilon \sigma^{\varepsilon\eta} \rightarrow \sigma^* \quad \text{in } L^2(0, T, L^2(\Omega)), \quad (5.15)$$

$$u_1^{\varepsilon\eta} \rightharpoonup^* u_1^*, \quad u_2^{\varepsilon\eta} \rightharpoonup^* 0, \quad \varepsilon \sigma^{\varepsilon\eta} \rightarrow \sigma^* \quad \text{in } L^\infty(0, T, L^2(\Omega)). \quad (5.16)$$

Proof. Summing (5.3), (5.8) implies that for ε small enough (i.e. if assumption (5.12) is satisfied):

$$\begin{aligned} & r\nu\rho \frac{d}{dt} (|v_1^{\varepsilon\eta}|^2 + |\varepsilon v_2^{\varepsilon\eta}|^2) + \frac{\lambda^*}{2\varepsilon} \frac{d}{dt} (|\tau_{11}^{\varepsilon\eta}|^2 + 2|\tau_{12}^{\varepsilon\eta}|^2 + |\tau_{22}^{\varepsilon\eta}|^2) + \frac{\eta}{\varepsilon} (|\nabla_\varepsilon \tau_{11}^{\varepsilon\eta}|^2 + 2|\nabla_\varepsilon \tau_{12}^{\varepsilon\eta}|^2 + |\nabla_\varepsilon \tau_{22}^{\varepsilon\eta}|^2) \\ & + \frac{r(1-r)\nu^2}{2} \left(|\partial_x v_1^{\varepsilon\eta}|^2 + \left| \frac{1}{\varepsilon} \partial_z v_1^{\varepsilon\eta} \right|^2 + |\varepsilon \partial_x v_2^{\varepsilon\eta}|^2 + |\partial_z v_2^{\varepsilon\eta}|^2 \right) + \frac{1}{2} \left| \frac{1}{\varepsilon} \tau_{11}^{\varepsilon\eta} \right|^2 + \left| \frac{1}{\varepsilon} \tau_{12}^{\varepsilon\eta} \right|^2 + \frac{1}{2} \left| \frac{1}{\varepsilon} \tau_{22}^{\varepsilon\eta} \right|^2 \leq C. \end{aligned} \quad (5.17)$$

From this inequality, it follows that $\mathbf{v}^{\varepsilon\eta}$ converges to \mathbf{v}^ε in $\mathbf{H}^1(\Omega)$ and $\boldsymbol{\tau}^{\varepsilon\eta}$ converges to $\boldsymbol{\tau}^\varepsilon$ in $\mathbf{L}^2(\Omega)$, as η tends to zero. \mathbf{v}^ε and $\boldsymbol{\tau}^\varepsilon$ are the solutions of (5.1) without the terms $\eta\Delta\boldsymbol{\tau}^{\varepsilon\eta}$. Indeed, recalling the weak formulation of the system (5.1), it suffices to notice that Hlder's inequality allows to treat the term $\eta\Delta\boldsymbol{\tau}^{\varepsilon\eta}$:

$$\eta \int_\Omega \nabla_\varepsilon \boldsymbol{\tau}^{\varepsilon\eta} \cdot \nabla_\varepsilon \boldsymbol{\phi} \leq \eta^{1/2} \left(\underbrace{|\nabla_\varepsilon \boldsymbol{\tau}^{\varepsilon\eta}|^2}_{\leq C} + |\nabla_\varepsilon \boldsymbol{\phi}|^2 \right) \xrightarrow{\eta \rightarrow 0} 0, \quad \forall \boldsymbol{\phi} \in \mathbf{H}_0^1(\Omega).$$

Moreover, \mathbf{v}^ε and $\boldsymbol{\tau}^\varepsilon$ satisfy the following estimate:

$$\begin{aligned} & r\nu\rho \frac{d}{dt} (|v_1^\varepsilon|^2 + |\varepsilon v_2^\varepsilon|^2) + \frac{\lambda^*}{2\varepsilon} \frac{d}{dt} (|\tau_{11}^\varepsilon|^2 + 2|\tau_{12}^\varepsilon|^2 + |\tau_{22}^\varepsilon|^2) \\ & + \frac{1}{2} r(1-r)\nu^2 \left(|\partial_x v_1^\varepsilon|^2 + \left| \frac{1}{\varepsilon} \partial_z v_1^\varepsilon \right|^2 + |\varepsilon \partial_x v_2^\varepsilon|^2 + |\partial_z v_2^\varepsilon|^2 \right) + \frac{1}{2} \left| \frac{1}{\varepsilon} \tau_{11}^\varepsilon \right|^2 + \left| \frac{1}{\varepsilon} \tau_{12}^\varepsilon \right|^2 + \frac{1}{2} \left| \frac{1}{\varepsilon} \tau_{22}^\varepsilon \right|^2 \leq C. \end{aligned} \quad (5.18)$$

It remains to pass to the limit as ε tends to zero. After integrating (5.18) between 0 and T , it yields that

$\triangleright \|v_1^\varepsilon\|_{L^2(L^2)} \leq \|\partial_z v_1^\varepsilon\|_{L^2(L^2)} \leq C\varepsilon$, thus the following convergences hold in $L^2(0, T, L^2(\Omega))$ as ε tends to zero:

$$v_1^\varepsilon \rightarrow 0 \quad \text{and} \quad \partial_z v_1^\varepsilon \rightarrow 0. \quad (5.19)$$

From these convergences, it follows that $u_1^\varepsilon = u_1^* + v_1^\varepsilon \rightarrow u_1^*$ in $L^2(0, T, L^2(\Omega))$ and $\partial_z u_1^\varepsilon \rightarrow \partial_z u_1^*$ in $L^2(0, T, L^2(\Omega))$.

▷ $\|\partial_x v_1^\varepsilon\|_{L^2(L^2)} \leq C$, thus $\partial_x v_1^\varepsilon$ converges weakly in $L^2(0, T, L^2(\Omega))$. Now, since it is already known that $u_1^\varepsilon \rightarrow u_1^*$, it follows that $\partial_x u_1^\varepsilon \rightharpoonup \partial_x u_1^*$ in $L^2(0, T, L^2(\Omega))$.

▷ Similarly $\|v_2^\varepsilon\|_{L^2(L^2)} \leq \|\partial_z v_2^\varepsilon\|_{L^2(L^2)} \leq C$, thus $\varepsilon v_2^\varepsilon$ and $\varepsilon \partial_z v_2^\varepsilon$ converge strongly to zero in $L^2(0, T, L^2(\Omega))$, and thus $u_2^\varepsilon = \varepsilon u_2^* + \varepsilon v_2^\varepsilon \rightarrow 0$ in $L^2(0, T, L^2(\Omega))$, and $\partial_z u_2^\varepsilon \rightarrow 0$ in $L^2(0, T, L^2(\Omega))$.

▷ $\|\partial_x v_2^\varepsilon\|_{L^2(L^2)} \leq \frac{C}{\varepsilon}$, thus $\partial_x u_2^\varepsilon$ converges weakly in $L^2(0, T, L^2(\Omega))$. Since $u_2^\varepsilon \rightarrow 0$, it implies that $\partial_x u_2^\varepsilon \rightharpoonup 0$ in $L^2(0, T, L^2(\Omega))$.

▷ $\|\tau_{11}^\varepsilon\|_{L^2(L^2)}, \|\tau_{12}^\varepsilon\|_{L^2(L^2)}, \|\tau_{22}^\varepsilon\|_{L^2(L^2)} \leq C\varepsilon$, therefore $\tau_{11}^\varepsilon, \tau_{12}^\varepsilon, \tau_{22}^\varepsilon \rightarrow 0$ in $L^2(0, T, L^2(\Omega))$. Thus $\varepsilon \sigma_{11}^\varepsilon = \sigma_{11}^* + \tau_{11}^\varepsilon \rightarrow \sigma_{11}^*$ in $L^2(0, T, L^2(\Omega))$, and in the same way $\varepsilon \sigma_{12}^\varepsilon \rightarrow \sigma_{12}^*$ in $L^2(0, T, L^2(\Omega))$, $\varepsilon \sigma_{22}^\varepsilon \rightarrow \sigma_{22}^*$ in $L^2(0, T, L^2(\Omega))$.

▷ From the terms with the derivatives in time, using the fact that $\mathbf{v}^\varepsilon|_{t=0} = \mathbf{u}_0^\varepsilon - \mathbf{u}^* \in \mathbf{L}^2(\Omega)$ and $\boldsymbol{\tau}^\varepsilon|_{t=0} = \boldsymbol{\sigma}_0^\varepsilon - \boldsymbol{\sigma}^* \in \mathbf{L}^2(\Omega)$ are bounded independently of ε , we can conclude that

$$\|\mathbf{v}^\varepsilon\|_{L^\infty(L^2)} \leq C \quad \text{and} \quad \|\boldsymbol{\tau}^\varepsilon\|_{L^\infty(L^2)} \leq C\sqrt{\varepsilon}.$$

These estimates and the uniqueness of the limit imply that v_1^ε and $\varepsilon v_2^\varepsilon$ converge weakly-* in $L^\infty(0, T, L^2(\Omega))$ toward zero, and that $\boldsymbol{\tau}^\varepsilon$ converges strongly in $L^\infty(0, T, \mathbf{L}^2(\Omega))$ toward zero, which proves the last estimate (5.16). □

Note that in a simplified case (with a simpler geometry), the hypothesis (5.12) is satisfied under a small data assumption on the physical parameters.

Remark 5.5. When h is constant with respect to x , p^* is also independent of x , so that equation (4.1) reduces to

$$-(1-r)\partial_z^2 u_1^* - r \frac{\partial}{\partial z} \left(\frac{\partial_z u_1^*}{1 + \lambda^{*2} |\partial_z u_1^*|^2} \right) = 0.$$

It has been shown in [8] for example that for $r < 8/9$ this equation admits a unique solution $u_1^* = s(1 - \frac{z}{h})$.

Now, it follows that $\sigma_{12}^* = \frac{r\nu\partial_z u_1^*}{1 + \lambda^{*2} |\partial_z u_1^*|^2} = \frac{-r\nu s}{h + \lambda^{*2} s^2/h}$, and $\sigma_{11}^* = -\sigma_{22}^* = -\lambda^* \partial_z u_1^* \sigma_{12}^* = \frac{-r\nu s^2 \lambda^*}{h^2 + \lambda^{*2} s^2}$.

In this case, hypothesis (5.12) becomes more simple. Since $\partial_z u_1^* = -s/h$, σ_{11}^* and σ_{12}^* are constant with respect to z , so that the last two conditions are trivially verified. Using the fact that $r < 8/9$, it leads to a smallness condition on $s\lambda^*$ with respect to h ($s\lambda^* \leq h/12$ is enough in order to satisfy all conditions).

Observe that this condition is not optimal, but it shows that in the simplified case when $h(x)$ is constant, a simple choice of the parameters s , λ^* and h satisfies hypothesis (5.12).

5.3 Convergence of the pressure

It remains to prove the convergence of the pressure.

Theorem 5.6. *Under the same smallness assumption (5.12), the following convergence result holds up to a subsequence for p :*

$$\varepsilon^2 p \xrightarrow{\varepsilon \rightarrow 0} p^* \quad \text{in } \mathcal{D}'(0, T, L^2(\Omega)). \quad (5.20)$$

Proof. Throughout the proof, C will denote some generic constants independent of ε . Let $\varepsilon \leq 1$. Let us integrate over $\Omega_T = \Omega \times (0, T)$ equation (5.1a) multiplied by $\varepsilon^2 \varphi_1$, for any function $\phi_1 \in H_0^1(\Omega)$. It follows:

$$\begin{aligned} \rho \varepsilon^2 \int_{\Omega_T} \partial_t v_1 \phi_1 + \rho \varepsilon^2 \int_{\Omega_T} v_1 \partial_x v_1 \phi_1 + \rho \varepsilon \int_{\Omega_T} v_2 \partial_z v_1 \phi_1 + (1-r) \nu \varepsilon^2 \int_{\Omega_T} \partial_x v_1 \partial_x \phi_1 + (1-r) \nu \int_{\Omega_T} \partial_z v_1 \partial_z \phi_1 \\ + \int_{\Omega_T} \partial_x q \phi_1 = -\varepsilon \int_{\Omega_T} \tau_{11} \partial_x \phi_1 - \int_{\Omega_T} \tau_{12} \partial_z \phi_1 + \varepsilon^2 \int_{\Omega_T} L_1 \phi_1 + \varepsilon \int_{\Omega_T} C_1 \phi_1, \quad \forall \phi_1 \in H_0^1(\Omega). \end{aligned} \quad (5.21)$$

Using the fact that ϕ_1 is independent of t , the first term becomes

$$\rho \varepsilon^2 \int_{\Omega_T} \partial_t v_1 \phi_1 = \rho \varepsilon^2 \int_{\Omega} \phi_1 \int_0^T \partial_t v_1 = \rho \varepsilon^2 \int_{\Omega} \phi_1 (v_1(T) - v_1(0)),$$

where $v_1(0) = u_{10} - u_1^*$ denotes the value of v_1 at time $t = 0$. Now, introducing

$$\pi = \int_0^T q \, dt,$$

and using integration by parts for the pressure term (the boundary term is zero since $\phi_1 \in H_0^1(\Omega)$), (5.21) becomes: $\forall \phi_1 \in H_0^1(\Omega)$,

$$\begin{aligned} \rho \varepsilon^2 \int_{\Omega} \phi_1 (v_1(T) - v_1(0)) + \rho \varepsilon^2 \int_{\Omega_T} v_1 \partial_x v_1 \phi_1 + \rho \varepsilon \int_{\Omega_T} r_2 \partial_z v_1 \phi_1 + (1-r) \nu \varepsilon^2 \int_{\Omega_T} \partial_x v_1 \partial_x \phi_1 \\ + (1-r) \nu \int_{\Omega_T} \partial_z v_1 \partial_z \phi_1 - \int_{\Omega} \pi \partial_x \phi_1 = -\varepsilon \int_{\Omega_T} \tau_{11} \partial_x \phi_1 - \int_{\Omega_T} \tau_{12} \partial_z \phi_1 + \varepsilon^2 \int_{\Omega_T} L_1 \phi_1 + \varepsilon \int_{\Omega_T} C_1 \phi_1. \end{aligned}$$

It remains to estimate all terms independent of π . The non-linear terms are to be handled with care, since $\phi_1 \notin L^\infty(\Omega)$. Proceeding as in [3], Hlder inequality with exponents $2 + \delta$, δ' and 2

leads:

$$\left| \int_{\Omega_T} v_1 \partial_x v_1 \phi_1 \right| \leq |\phi_1|_{\delta'} \int_0^T |v_1|_{2+\delta} |\partial_x v_1|, \quad (5.22)$$

where $\frac{1}{2+\delta} + \frac{1}{2} + \frac{1}{\delta'} = 1$ (which implies that $\delta' = \frac{2(2+\delta)}{\delta}$). According to interpolation theory, $[L^2, L^4]_\theta = L^{2+\delta}$ for $\theta = \frac{\delta}{2+\delta}$, and the following estimate holds:

$$|v_1|_{2+\delta} \leq C |v_1|_4^\theta |v_1|^{1-\theta}.$$

Moreover Lemma 3.2 of [1] states that for $v_1 \in H_0^1(\Omega)$, it holds:

$$|v_1|_4 \leq \sqrt{2} |\partial_x v_1|^{1/4} |\partial_z v_1|^{3/4}.$$

Using the two last inequalities and Poincar inequality, (5.22) becomes

$$\rho \varepsilon^2 \left| \int_{\Omega_T} v_1 \partial_x v_1 \phi_1 \right| \leq \rho \varepsilon^2 |\phi_1|_{\delta'} C \int_0^T |\partial_x v_1|^{\theta/4} |\partial_z v_1|^{3\theta/4} |\partial_z v_1|^{1-\theta} |\partial_x v_1|,$$

and Hlder inequality implies that

$$\rho \varepsilon^2 \int_{\Omega_T} v_1 \partial_x v_1 \phi_1 \leq \rho \varepsilon^2 |\phi_1|_{\delta'} C \|\partial_x v_1\|_{L^2(\Omega_T)}^{1+\theta/4} \|\partial_z v_1\|_{L^2(\Omega_T)}^{1-\theta/4}.$$

Now, choose θ (and thus δ) such that $\delta' \geq 6$. It suffices to take $\theta \leq \frac{1}{3}$, for example take $\theta = \frac{1}{3}$. Then $\delta' = 6$, and the usual Sobolev embeddings read $H^1(\Omega) \hookrightarrow L^6(\Omega)$ (which is true in dimension 2 or 3). Therefore, the last estimate becomes

$$\rho \varepsilon^2 \int_{\Omega_T} v_1 \partial_x v_1 \phi_1 \leq \rho \varepsilon^2 C \|\phi_1\|_{H^1} \|\partial_x v_1\|_{L^2(\Omega_T)}^{13/12} \|\partial_z v_1\|_{L^2(\Omega_T)}^{11/12}.$$

Now, recalling that $\|\partial_z v_1\|_{L^2(L^2)} \leq C\varepsilon$ and $\|\partial_x v_1\|_{L^2(L^2)} \leq C$, we conclude

$$\rho \varepsilon^2 \int_{\Omega_T} v_1 \partial_x v_1 \phi_1 \leq \rho \varepsilon^2 C \|\phi_1\|_{H^1} \varepsilon^{11/12} = \rho \varepsilon^{2+11/12} C \|\phi_1\|_{H^1} \leq C\varepsilon \|\phi_1\|_{H^1}.$$

In a similar way, it holds

$$\rho \varepsilon \int_{\Omega_T} r_2 \partial_z v_1 \phi_1 \leq \rho \varepsilon^{2-1/12} C \|\phi_1\|_{H^1} \leq \tilde{C} \varepsilon \|\phi_1\|_{H^1}.$$

For the term $\rho \varepsilon^2 \int_{\Omega} \phi_1 (v_1(T) - v_1(0))$, we apply Cauchy-Schwarz inequality. $v_1(0)$ is bounded, and

for $v_1(T)$, we use Poincar inequality. It follows, using the fact that $|\partial_z v_1| \leq C\varepsilon$:

$$\rho\varepsilon^2 \int_{\Omega} \phi_1(v_1(T)-v_1(0)) \leq (C|v_1|+C)\varepsilon^2 \|\phi_1\|_{H^1} \leq (C|\partial_z v_1|+C)\varepsilon^2 \|\phi_1\|_{H^1} \leq C\varepsilon^2 \|\phi_1\|_{H^1} \leq C\varepsilon \|\phi_1\|_{H^1}.$$

For the other linear terms, a simple application of Cauchy-Schwarz inequality allows to obtain similar estimates. Indeed, it suffices to use the estimate (5.18) in order to estimate the L^2 -norm of $\partial_x v_1$, $\partial_z v_1$, τ_{11} , τ_{12} , L_1 , C_1 . For example, since $|\partial_x v_1| \leq C$, the following estimate holds:

$$\rho\varepsilon^2 \int_{\Omega} \partial_x v_1 \partial_x \phi_1 \leq \rho\varepsilon^2 |\partial_x v_1| |\partial_x \phi_1| \leq C\varepsilon^2 \|\phi_1\|_{H^1}.$$

For the terms L_1 and C_1 , C_1 and the constant part of L_1 are obviously bounded uniformly in ε . It remains to estimate the linear term \mathcal{L}_1 of L_1 . Recalling its definition and using Poincar inequality in the second estimate:

$$|\mathcal{L}_1| \leq C(|v_1| + |v_2| + |\partial_x v_1| + |\partial_z v_1|) \leq C(|\partial_z v_1| + |\partial_x v_1| + |\partial_z v_2|).$$

Using again (5.18), the boundedness of \mathcal{L}_1 follows:

$$|\mathcal{L}_1| \leq C.$$

Hence $\forall \phi_1 \in H_0^1(\Omega)$:

$$\int_{\Omega} \partial_x \pi \phi_1 \leq C(\varepsilon + \varepsilon^2 |\partial_x v_1| + |\partial_z v_1| + \varepsilon |\tau_{11}| + |\tau_{12}| + \varepsilon^2 |L_1| + \varepsilon |C_1|) \|\phi_1\|_{H^1} \leq C\varepsilon \|\phi_1\|_{H^1}.$$

The same approach with (5.1b) gives a similar estimate, for all $\phi_2 \in H_0^1(\Omega)$:

$$\int_{\Omega} \partial_z \pi \phi_2 \leq C(\varepsilon + \varepsilon^4 |\partial_x v_2| + \varepsilon^2 |\partial_z v_2| + \varepsilon^2 |\tau_{12}| + \varepsilon |\tau_{22}| + \varepsilon^2 |L_2| + \varepsilon |C_2|) \|\phi_2\|_{H^1} \leq C\varepsilon \|\phi_2\|_{H^1}.$$

Thus we can conclude that $\|\nabla \pi\|_{L^\infty(H^{-1})} \leq C\varepsilon$.

Now recall that for $f \in L_0^2(\Omega)$, it holds that $|f| \leq \|\nabla q\|_{H^{-1}}$ (see for example [17]). Since $p \in L_0^2(\Omega)$ and $p^* \in L_0^2(\Omega)$, q lies in $L_0^2(\Omega)$. From the definition of π as function of q , it is clear that $\pi \in L_0^2(\Omega)$.

This allows to deduce

$$|\pi|_{L^\infty(L^2)} \leq \|\nabla \pi\|_{L^\infty(H^{-1})} \leq C\varepsilon \rightarrow 0,$$

thus π tends to zero in $L^\infty(0, T, L_0^2(\Omega))$ when $\varepsilon \rightarrow 0$. Now, since $q = \frac{\partial \pi}{\partial t}$, it follows that q tends to zero in $\mathcal{D}'(0, T, L_0^2(\Omega))$, and therefore:

$$\varepsilon^2 p \xrightarrow{\varepsilon \rightarrow 0} p^* \quad \text{in } \mathcal{D}'(0, T, L^2(\Omega)).$$

This finishes the proof. \square

5.4 Open problems

This work concerns only the solutions of the problem (3.1) that are obtained as the limit of the regularized problem we chose (with an additional term $-\eta\Delta\sigma$). Since there is no uniqueness result for problem (3.1), it is not known how other solutions behave.

Formally, the passing to the limit can be done for $a \neq 0$ (see [4]), and a similar limit problem (involving the parameter a , but of the same structure). However, the proof of the existence theorem in $\hat{\Omega}^\varepsilon$ strongly relies on the fact that $a = 0$. No global results are proved in the case $a \neq 0$.

Last, since the computations are independent of the dimension of the domain Ω , the result should be true in the three-dimensional case. The limit problem on $(\mathbf{u}^*, p^*, \sigma^*)$ reads:

$$\left\{ \begin{array}{l} (1-r)\nu\partial_z^2 u_1^* - \partial_x p^* + \partial_z \sigma_{13}^* = 0, \\ (1-r)\nu\partial_z^2 u_2^* - \partial_x p^* + \partial_z \sigma_{23}^* = 0, \\ \partial_z p^* = 0, \\ \nabla \cdot \mathbf{u}^* = 0, \\ -\lambda^* \partial_z u_1^* \sigma_{13}^* + \sigma_{11}^* = 0, \\ -\frac{\lambda^*}{2} \partial_z u_1^* \sigma_{13}^* - \partial_z u_2^* \sigma_{23}^* + \sigma_{12}^* = 0, \\ -\lambda^* \partial_z u_2^* \sigma_{23}^* + \sigma_{22}^* = 0, \\ \frac{\lambda^*}{2} \partial_z u_2^* (\sigma_{33}^* - \sigma_{22}^*) - \frac{\lambda^*}{2} \partial_z u_1^* \sigma_{12}^* + \sigma_{23}^* = r\nu\partial_z u_2^*, \\ \lambda^* (\partial_z u_1^* \sigma_{13}^* + \partial_z u_2^* \sigma_{23}^*) + \sigma_{33}^* = 0, \\ \frac{\lambda^*}{2} \partial_z u_1^* (\sigma_{33}^* - \sigma_{11}^*) - \frac{\lambda^*}{2} \partial_z u_2^* \sigma_{12}^* + \sigma_{12}^* = r\nu\partial_z u_1^*. \end{array} \right. \quad (5.23)$$
